Received January 2005

The object-calculus is an imperative and object-based programming language where every object comes equipped with its own method suite. Consequently, methods need to reside in the store (“higher-order store”) which complicates the semantics. Abadi and Leino defined a program logic for this language enriching object types by method specifications. We present a new soundness proof for their logic using Denotational Semantics. It turns out that denotations of store specifications are predicates defined by mixed-variant recursion. A benefit of our approach is that derivability and validity can be kept distinct. Moreover, it is revealed which of the limitations of Abadi and Leino’s logic are incidental design decisions and which follow inherently from the use of higher-order store. We discuss the implications for the development of other, more expressive, program logics.

1. Introduction and Motivation

When Hoare presented his seminal work about an *axiomatic basis of computer programming* (Hoare, 1969), high-level languages had just started to gain broader acceptance. Meanwhile programming languages are evolving ever more rapidly, whereas verification techniques seem to be struggling to keep up. For object-oriented languages several formal systems have been proposed, e.g. (Abadi and Leino, 2004; Hensel et al., 1998; Jacobs and Poll, 2001; Reddy, 2002; Poetzsch-Heffter and Müller, 1999; de Boer, 1999; von Oheimb, 2001; Reus et al., 2001). A “standard” comparable to the Hoare-calculus for imperative WHILE-languages (Apt, 1981) has not yet emerged. Nearly all the approaches listed above are designed for class-based languages (usually a sub-language of sequential Java), where method code is known statically.

One notable exception is the work of Abadi and Leino (1997; 2004) where a logic for an object-based language is introduced that is derived from the imperative object calculus with first-order types, **imp ς** , of Abadi and Cardelli (1996). In object-based languages,

[†] This work was supported by the EPSRC under grant GR/R65190/01, “Programming Logics for Denotations of Recursive Objects”

every object contains its own suite of methods. Operationally speaking, the store for such a language contains code and is thus often called *higher-order store*.

The fact that methods are stored like any other data inside objects means that new code can be added at all times, yielding compositionality of components (here objects) for free. By contrast, classical fixpoint-based semantics for classes (or modules) is “closed” in the sense that it cannot model the addition of previously unknown classes in a compositional way. As classes can be compiled into objects (Abadi and Cardelli, 1996), and object-based languages provide this kind of compositionality, higher-order store semantics can naturally deal with classes defined on-the-fly, like inner classes and classes loaded at run-time (cf. Reus, 2002; Reus, 2003).

Abadi and Leino’s logic is a Hoare-style system, dealing with partial correctness of object expressions. Their idea was to enrich object types by method specifications, also called *transition relations*, relating pre- and post-execution states of program statements, and *result specifications* describing the result in case of program termination. Informally, an object satisfies such a specification

$$A \equiv [f_i: A_i^{i=1\dots n}, m_j: \zeta(y_j)B_j::T_j^{j=1\dots m}]$$

if it has fields f_i satisfying A_i and methods m_j that satisfy the transition relation T_j and, in case of termination of the method invocation, their result satisfies B_j . However, just as a method can use the *self*-parameter, we can assume that an object a itself satisfies A in both B_j and T_j when establishing that A holds for a . This yields a powerful and convenient proof principle for objects. [†]

We are going to present a new soundness proof for this logic using an untyped denotational semantics of the language and the logic to define validity. Every program and every specification has a meaning, a *denotation*. Those of specifications are simply predicates on (the domain of) objects. The properties of these predicates provide a description of inherent limitations of the logic. Such an approach is not new, for instance it has been used in LCF, a logic for functional programs (Paulson, 1987).

The difficulty in this case is to establish predicates that provide the powerful reasoning principle for objects. Reus and Streicher (2004) have outlined how to use some classic domain theory (Pitts, 1996) to guarantee existence and uniqueness of appropriate predicates on isolated objects. In an object-calculus program, however, an object may depend on other objects and their respective methods in the store. So object specifications must depend on specifications of other objects in the store which gives rise to “store specifications”. Indeed store specifications were already present in the operationally-based work of Abadi and Leino.

This paper is, therefore, not merely an application of the ideas in (Reus and Streicher, 2004). Much care is needed to establish the important invariance property of Abadi-Leino logic, namely that proved programs preserve store specifications. Our main achievement, in a nutshell, is that we have successfully applied the ideas of Reus and Streicher (2004)

[†] In class-based languages one can provide an analogous proof principle when using higher-order store (see Kamin and Reddy, 1994). In a closed-world scenario, however, where (mutually recursive) classes are known altogether at verification time, fixpoint induction suffices as proof principle.

to the logic of Abadi and Leino (2004). We obtain a more useful and more instructive soundness proof, complementary to the one of Abadi and Leino (2004), for the following reasons:

- 1 Abadi and Leino employ an operational semantics where stores contain method *syntax* that can be used in derivations again. This allows them to get away with having no semantics for store specifications at all. Validity for judgements is w.r.t. initial stores whose methods are assumed to have been *derived correct* w.r.t. some store specification. Consequently, validity (of judgements) depends on derivability (for store specifications). This approach can be justified under the assumption that only verified methods reside in initial stores. Alas, it prevents them from using induction on derivations of judgements so they are forced to use induction on derivations of the (small-step) semantics of the judgement's program instead. As the subsumption rule is not triggered by program syntax, it has to be considered in all cases and clutters the soundness proof.

On the other hand, by using a Denotational Semantics, we *can* provide a (necessarily recursive) semantics for store specifications and keep validity and derivability distinct. This has the additional advantage of a canonical treatment of the subsumption rule. We can also define a semantics of object specifications and show how it relates to store specifications. Note that our approach would also work for stores containing method syntax as it can be interpreted in a big step operational semantics.

- 2 We can easily extend the logic, for instance by recursive specifications. Fold and unfold can in our approach be handled by subsumption rules which are problematic in the original proof (see 1). A similar extension has been done for the Abadi-Leino logic by Leino (1998), but for a slightly different language with *nominal* rather than structural subtyping.
- 3 Essential restrictions of object logics in general are revealed and distinguished from idiosyncratic shortcomings of the Abadi-Leino logic. For example, in (Abadi and Leino, 2004) transition specifications cannot talk about methods at all (see also Section 7). Our semantics shows that this is not necessary, although certain conditions must be met by the specification language in order to show the existence of the recursive store specifications.

That specifications are preserved by verified programs is a consequence of the idea of enriching types and disallowing method update. It relieves the verifier from carrying around specifications of (parts of) the store. Unfortunately, it enforces a global verification regime and prohibits method and specification updates. Making assumptions about store explicit is a remedy. This may sound tedious, but employing local reasoning principles like those of *Separation Logic* (for an overview see e.g. (O'Hearn et al, 2001; Reynolds, 2002)), it should not be. Our denotational semantics directly supports such an explicit handling of store specifications.

Problems that are inherent to object logics (or logics for higher-order store) are the need for (recursive) store specifications, and invariance of field types in the definition of subspecification. Our proof still refers to syntactic store specifications as programs will not preserve arbitrary predicates on stores. We do not know of a way to describe

Table 1. *Syntax*

a, b	$::=$	x	variable
		true false	booleans
		if x then a else b	conditional
		let $x = a$ in b	let
		$[f_i = x_i^{i=1\dots n}, m_j = \varsigma(y_j)b_j^{j=1\dots m}]$	object construction
		$x.f$	field selection
		$x.f := y$	field update
		$x.m$	method invocation

semantically those programs of a specific programming language that are verifiable in a specific logic.

- 4 Our work provides an alternative description of difficulties inherent in programming logics for objects. Therefore, it may be appealing to semanticists and domain theorists. It may be useful to *develop and analyse similar, but more powerful, program logics* as well.

The outline of this article is as follows. In the next section, syntax and semantics of the object calculus are presented. Section 3 introduces the Abadi-Leino logic and the denotational semantics of its object specifications. It follows a discussion about store specifications and their semantics (Section 4). The main result is in Section 5 where the logic is proved sound. Finally, we sketch how recursive specifications can be introduced (Section 6) and discuss further extensions (Section 7). A summary concludes the paper (Section 8).

An extended abstract of this article has appeared as (Reus and Schwinghammer, 2005).

2. The Object Calculus

Below, we recall the language used in (Abadi and Leino, 2004), which is based on the imperative object calculus of Abadi and Cardelli (1996). Following Reus and Streicher (2004) we give a denotational semantics to this language in Section 2.2.

2.1. *Syntax*

Let \mathcal{V} , \mathcal{M} and \mathcal{F} be pairwise disjoint, countably infinite sets of *variables*, *method names* and *field names*, respectively. Let x, y range over \mathcal{V} , let $m \in \mathcal{M}$ and $f \in \mathcal{F}$. The language is defined by the grammar in Table 1.

Variables are (immutable) identifiers, the semantics of booleans and conditional is as usual. The object expression **let** $x = a$ **in** b first evaluates a and then evaluates b with the result of a bound to x .

Object construction $[f_i = x_i^{i=1\dots n}, m_j = \varsigma(y_j)b_j^{j=1\dots m}]$ allocates new storage and returns a reference to an object containing fields f_i (with initial value the value of x_i) and methods m_j . In a method $m_j = \varsigma(y_j)b_j$, ς is a binder that binds the explicit self parameter y_j in the method body b_j . During method invocation, the method body is evaluated

with the self parameter bound to the host object. We identify objects that differ only in the names of bound variables and the order of components.

The result of field selection $x.f$ is the value of the field, and $x.f := y$ is field update. A formal semantics is given in the next subsection below.

Note that in contrast to Abadi and Cardelli's (1996) calculus this language distinguishes between fields and methods, and that method update is disallowed. Also note that we restrict the cases for field selection, field update, method invocation and if statement to contain only variables as subterms (instead of arbitrary object terms). This is no real limitation because of the let construct, but it simplifies the statement of the rules of the logic (Abadi and Leino, 2004). We use a more generous syntax (for instance, also allowing for natural numbers) in the examples.

Example 2.1. We extend the syntax with integer constants and operations, and consider an object-based modelling of a bank account as an example:

```
acc(x) ≡ [balance = 0,
         deposit10 = ζ(y) let z = y.balance+10 in y.balance:=z,
         interest = ζ(y) let r = x.manager.rate in
                 let z = y.balance*r/100 in y.balance:=z]
```

Note how the self parameter y is used in both methods to access the `balance` field. Object `acc` depends on a “managing” object x in the context that provides the interest rate, through a field `manager`, for the `interest` method.

2.2. Semantics of Objects

2.2.1. Preliminaries We work in the category \mathbf{pCpo} of ω -complete partial orders (not necessarily containing a least element) and partial continuous functions. [‡] Let $A \rightarrow B$ denote the partial continuous function space between cpos A and B . For $f \in A \rightarrow B$ and $a \in A$ we write $f(a) \downarrow$ if f applied to a is defined, and $f(a) \uparrow$ otherwise.

If L is a set, then $\mathcal{P}(L)$ is its powerset, $\mathcal{P}_{\text{fin}}(L)$ denotes the set of its finite subsets, and A^L is the set of all *total* functions from L to A . For a countable set \mathbb{L} and a cpo A we write

$$\text{Rec}_{\mathbb{L}}(A) = \sum_{L \in \mathcal{P}_{\text{fin}}(\mathbb{L})} A^L$$

for the cpo of *records* with *entries* from A and *labels* from \mathbb{L} . Note that $\text{Rec}_{\mathbb{L}}$ extends to a locally continuous endofunctor on \mathbf{pCpo} . Further note that, in the natural partial order on records defined this way, only records with equal domain are comparable; in particular, a record and its extensions are *incomparable*.

A record $(L, f \in A^L)$, with labels $L = \{l_1, \dots, l_n\}$ and corresponding entries $f(l_i) = a_i$, is written as $\{l_1 = a_1, \dots, l_n = a_n\}$. Update (and extension) of records is defined as the

[‡] Other categories of domains could be used; our results only rely on the existence of minimal invariant solutions to recursive domain equations (Pitts, 1996).

corresponding operation on functions, i.e.,

$$\{\{l_i = a_i^{i=1\dots n}\}[l := a]\} = \begin{cases} \{l_1 = a_1, \dots, l_k = a, \dots, l_n = a_n\} & \text{if } l = l_k \text{ for some } k \\ \{l_i = a_i^{i=1\dots n}, l = a\} & \text{otherwise} \end{cases}$$

Selection of a label $l \in \mathbb{L}$ of a record $r \in \text{Rec}_{\mathbb{L}}(A)$ is written $r.l$. It is defined and yields $f(l)$ if r is $(D, f \in A^D)$ and $l \in D$.

2.2.2. Interpretation The language of the previous section finds its interpretation within the following system of recursively defined cpos in **pCpo**

$$\begin{aligned} \text{Val} &= \text{BVal} + \text{Loc} \\ \text{St} &= \text{Rec}_{\text{Loc}}(\text{Ob}) \\ \text{Ob} &= \text{Rec}_{\mathcal{F}}(\text{Val}) \times \text{Rec}_{\mathcal{M}}(\text{Cl}) \\ \text{Cl} &= \text{St} \rightarrow (\text{Val} + \{\text{error}\}) \times \text{St} \end{aligned} \tag{1}$$

Here, **Loc** is some countably infinite set of *locations* ranged over by l , and **BVal** is the set of truth values *true* and *false*. Both are discrete partial orders and thus complete. Objects in **Ob** are pairs, consisting of a record that assigns values to the fields of the object, and a record associating *closures* to method names. Each closure is modelled as a partial map in **Cl**. In case of termination, result value and resulting store are returned by the closure; exceptional termination is indicated by returning *error*. Finally, the cpo **St** models stores as finite records of objects, indexed by locations.

Consider the functor $F_{\text{Store}} : \mathbf{pCpo}^{op} \times \mathbf{pCpo} \rightarrow \mathbf{pCpo}$ obtained from (1) by solving the system of equations for **St**, and separating positive and negative occurrences of **St** on the right-hand side:

$$F_{\text{Store}}(S, T) = \text{Rec}_{\text{Loc}}(\text{Rec}_{\mathcal{F}}(\text{Val}) \times \text{Rec}_{\mathcal{M}}(S \rightarrow (\text{Val} + \{\text{error}\}) \times T))$$

This is a locally continuous bifunctor. So there exists a minimal invariant solution **St** to this system of equations, i.e., $F_{\text{Store}}(\text{St}, \text{St}) = \text{St}$ and moreover the identity on **St** is the least fixed point of the map $\delta(e) = F(e, e)$ (for instance, see Pitts, 1996, and Smyth and Plotkin, 1982).

Let $\text{Env} = \mathcal{V} \rightarrow_{\text{fin}} \text{Val}$ be the set of *environments*, i.e. maps between \mathcal{V} and **Val** with finite domain. Given an environment $\rho \in \text{Env}$, the interpretation $\llbracket a \rrbracket \rho$ of an object expression a in $\text{St} \rightarrow (\text{Val} + \{\text{error}\}) \times \text{St}$ is given in Table 2. Here we use a (semantic) strict **let** that is also “strict” with respect to *error*:

$$\mathbf{let} (v, \sigma) = s \mathbf{in} s' \equiv \begin{cases} \text{undefined} & \text{if } s \text{ is undefined} \\ (\text{error}, \sigma') & \text{if } s = (\text{error}, \sigma') \\ (\lambda(v, \sigma).s') s & \text{otherwise} \end{cases}$$

Note that for $o \in \text{Ob}$ we just write $o.f$ and $o.m$ instead of $\pi_1(o).f$ and $\pi_2(o).m$, respectively. Similarly, we omit the injections for elements of $\text{Val} + \{\text{error}\}$, writing simply l instead of $\text{in}_{\text{Loc}}(l)$ etc. Observe that, in contrast to Reus and Streicher (2004), we distinguish between non-termination (undefinedness) and exceptional termination (*error*); the latter represents dynamic type errors and null-pointer dereferencing. Finally, because **Loc** is

Table 2. Denotational semantics

$\llbracket x \rrbracket_{\rho\sigma}$	$=$	$\begin{cases} (\rho(x), \sigma) & \text{if } x \in \text{dom}(\rho) \\ (\text{error}, \sigma) & \text{otherwise} \end{cases}$
$\llbracket \text{true} \rrbracket_{\rho\sigma}$	$=$	(true, σ)
$\llbracket \text{false} \rrbracket_{\rho\sigma}$	$=$	(false, σ)
$\llbracket \text{if } x \text{ then } b_1 \text{ else } b_2 \rrbracket_{\rho\sigma}$	$=$	$\begin{cases} \llbracket b_1 \rrbracket_{\rho\sigma'} & \text{if } \llbracket x \rrbracket_{\rho\sigma} = (\text{true}, \sigma') \\ \llbracket b_2 \rrbracket_{\rho\sigma'} & \text{if } \llbracket x \rrbracket_{\rho\sigma} = (\text{false}, \sigma') \\ (\text{error}, \sigma') & \text{if } \llbracket x \rrbracket_{\rho\sigma} = (v, \sigma') \text{ for } v \notin \text{BVal} \end{cases}$
$\llbracket \text{let } x = a \text{ in } b \rrbracket_{\rho\sigma}$	$=$	$\text{let } (v, \sigma') = \llbracket a \rrbracket_{\rho\sigma} \text{ in } \llbracket b \rrbracket_{\rho[x := v]\sigma'}$
$\llbracket [f_i = x_i^{i=1\dots n}, m_j = \varsigma(y_j)b_j^{j=1\dots m}] \rrbracket_{\rho\sigma}$	$=$	$\begin{cases} (l, \sigma[l := (o_1, o_2)]) & \text{if } x_i \in \text{dom}(\rho), 1 \leq i \leq n \\ (\text{error}, \sigma) & \text{otherwise} \end{cases}$ where $\begin{cases} l \notin \text{dom}(\sigma) \\ o_1 = \{f_i = \rho(x_i)^{i=1\dots n}\} \\ o_2 = \{m_j = \lambda\sigma. \llbracket b_j \rrbracket_{\rho[y_j := l]\sigma^{j=1\dots m}}\} \end{cases}$
$\llbracket x.f \rrbracket_{\rho\sigma}$	$=$	$\text{let } (l, \sigma') = \llbracket x \rrbracket_{\rho\sigma}$ $\text{in } \begin{cases} (\sigma'.l.f, \sigma') & \text{if } l \in \text{dom}(\sigma') \text{ and } f \in \text{dom}(\sigma'.l) \\ (\text{error}, \sigma') & \text{otherwise} \end{cases}$
$\llbracket x.f := y \rrbracket_{\rho\sigma}$	$=$	$\text{let } (l, \sigma') = \llbracket x \rrbracket_{\rho\sigma} \text{ in } \text{let } (v, \sigma'') = \llbracket y \rrbracket_{\rho\sigma'}$ $\text{in } \begin{cases} (l, \sigma''[l := \sigma''.l[f := v]]) & \text{if } l \in \text{dom}(\sigma'') \text{ and } f \in \text{dom}(\sigma''.l) \\ (\text{error}, \sigma'') & \text{otherwise} \end{cases}$
$\llbracket x.m \rrbracket_{\rho\sigma}$	$=$	$\text{let } (l, \sigma') = \llbracket x \rrbracket_{\rho\sigma}$ $\text{in } \begin{cases} \sigma'.l.m(\sigma') & \text{if } l \in \text{dom}(\sigma') \text{ and } m \in \text{dom}(\sigma'.l) \\ (\text{error}, \sigma') & \text{otherwise} \end{cases}$

assumed to be infinite, the condition $l \notin \text{dom}(\sigma)$ in the case for object creation can always be satisfied. Therefore object creation will never raise **error**.

A more subtle point is the choice of the location itself: In order for the interpretation $\llbracket a \rrbracket$ to be well-defined, a deterministic or parametric allocator has to be assumed (Section 5 of Banerjee and Naumann, 2005). For example, a deterministic allocator is the one that always chooses the minimal location (in an appropriate sense) amongst those available for allocation. A more sophisticated solution may be possible in the setting of FM-sets (Shinwell and Pitts, 2005; Benton and Leperchey, 2005). For a language with higher-order store this is an interesting research topic that needs further investigation.

2.2.3. Flat Stores We will make use of a projection to the part of the store that contains just data in **Val**, thus “forgetting” all closures of objects residing in the store: Let $\text{St}_{\text{Val}} = \text{Rec}_{\text{Loc}}(\text{Rec}_{\mathcal{F}}(\text{Val}))$, and define this projection $\pi_{\text{Val}} : \text{St} \rightarrow \text{St}_{\text{Val}}$ by

$$(\pi_{\text{Val}} \sigma).l.f = \sigma.l.f$$

for all $l \in \text{Loc}$ and $f \in \mathcal{F}$. We refer to $\pi_{\text{Val}}(\sigma)$ as the *flat part* of σ . Note that for all $\sigma, \sigma' \in \text{St}$,

$$\sigma \sqsubseteq \sigma' \implies \pi_{\text{Val}}(\sigma) = \pi_{\text{Val}}(\sigma')$$

since $\text{St}_{\text{Val}} = \text{Rec}_{\text{Loc}}(\text{Rec}_{\mathcal{F}}(\text{Val}))$ inherits the discrete order from **Val**.

3. Abadi-Leino Logic

We recall the logic of Abadi and Leino (2004) next. A slightly different presentation can be found in (Tang and Hofmann, 2002) where the proof system is given in a syntax-directed way.

3.1. Transition Relations and Specifications

Transition relations T correspond to the pre- and post-conditions of Hoare logic and allow to express state changes caused by computations. The syntax of transition relations is defined by the following grammar:

$$\begin{aligned} T & ::= e_0 = e_1 \mid \text{alloc}_{pre}(e) \mid \text{alloc}_{post}(e) \mid \neg T \mid T_0 \wedge T_1 \mid \forall x.T \\ e & ::= x \mid f \mid \text{result} \mid \text{true} \mid \text{false} \mid \text{sel}_{pre}(e_0, e_1) \mid \text{sel}_{post}(e_0, e_1) \end{aligned}$$

Expressions e range over variables $x \in \mathcal{V}$, field names $f \in \mathcal{F}$, constants **true**, **false** and **result** (which stands for the result value of a computation), and function symbol applications: Intuitively, the application $\text{sel}_{pre}(x, y)$ yields the value of field y of the object at location x before execution, provided this exists in the store, and is undefined otherwise. Correspondingly, $\text{sel}_{post}(x, y)$ gives the value of field y after execution. The predicates $\text{alloc}_{pre}(x)$ and $\text{alloc}_{post}(x)$ are true if the location x is allocated before and after the execution, respectively, and false otherwise. The notions of free and bound variables of a transition relation T carry over directly from first-order logic. As usual, further logical constants and connectives such as *True*, *False*, disjunction and implication can be defined as abbreviations.

Specifications combine transition relations for each method as well as the result types into a single specification for the whole object. They generalise the first-order types from (Abadi and Cardelli, 1996), and are

$$A, B \in \text{Spec} ::= \text{Bool} \mid [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$$

In the case of an object specification, ς in $\varsigma(y_j)B_j::A_j$ binds the variable y_j in B_j and T_j . Specifications are identified up to renaming of bound variables and reordering of components, which will be justified by our semantics.

Intuitively, **true** and **false** satisfy *Bool*, and an object satisfies the specification $A \equiv [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$ if it has fields f_i satisfying A_i and methods m_j that satisfy the transition relation T_j and, in case of termination of the method invocation, the result satisfies B_j . Corresponding to the fact that a method m_j can use the *self*-parameter y_j , in both T_j and B_j it is possible to refer to the ambient object y_j .

Let Γ range over *specification contexts* $x_1:A_1, \dots, x_n:A_n$. A specification context is *well-formed* if no variable x_i occurs more than once, and the free variables of A_k are contained in the set $\{x_1, \dots, x_{k-1}\}$. In writing $\Gamma, x:A$ we will always assume that x does not appear in Γ . Sometimes we write \emptyset for the empty context. Given Γ , we write $[\Gamma]$ for the list of variables occurring in Γ :

$$[x_1:A_1, \dots, x_n:A_n] = x_1, \dots, x_n$$

If clear from context, we use the notation \bar{x} for a sequence x_1, \dots, x_n , and similarly $\bar{x} : \bar{A}$

Table 3. Well-formed specifications and contexts

WFSPEC1	$\bar{x} \vdash \text{Bool}$
WFSPEC2	$\bar{x} \vdash A_i^{i=1\dots n} \quad \bar{x}, y_j \vdash B_j^{j=1\dots m} \quad \bar{x}, y_j \vdash T_j^{j=1\dots m}$ $\bar{x} \vdash [\mathbf{f}_i: A_i^{i=1\dots n}, \mathbf{m}_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$
WFCTXT1	$\emptyset \vdash \text{ok}$
WFCTXT2	$\Gamma \vdash \text{ok} \quad [\Gamma] \vdash A \quad x \notin \text{dom}(\Gamma)$ $\Gamma, x:A \vdash \text{ok}$

Table 4. Transition relations T_{res} , T_{obj} and T_{upd}

$T_{\text{res}}(e)$	\equiv	$\text{result} = e \wedge \forall x \forall f. (\text{alloc}_{\text{pre}}(x) \leftrightarrow \text{alloc}_{\text{post}}(x) \wedge \text{sel}_{\text{pre}}(x, f) = \text{sel}_{\text{post}}(x, f))$
$T_{\text{obj}}(\mathbf{f}_i = x_i)^{i=1\dots n}$	\equiv	$\neg \text{alloc}_{\text{pre}}(\text{result}) \wedge \text{alloc}_{\text{post}}(\text{result}) \wedge \bigwedge_{i=1\dots n} \text{sel}_{\text{post}}(\text{result}, \mathbf{f}_i) = x_i$ $\wedge \forall x \forall f. x \neq \text{result} \rightarrow (\text{alloc}_{\text{pre}}(x) \leftrightarrow \text{alloc}_{\text{post}}(x) \wedge \text{sel}_{\text{pre}}(x, f) = \text{sel}_{\text{post}}(x, f))$
$T_{\text{upd}}(x, f, e)$	\equiv	$\forall x'. \text{alloc}_{\text{pre}}(x') \leftrightarrow \text{alloc}_{\text{post}}(x') \wedge \text{sel}_{\text{post}}(x, f) = e \wedge \text{result} = x$ $\wedge \forall x' \forall f'. (x' \neq x \vee f' \neq f) \rightarrow \text{sel}_{\text{pre}}(x', f') = \text{sel}_{\text{post}}(x', f')$

for $x_1:A_1, \dots, x_n:A_n$. To make the notions of well-formed specifications and well-formed specification contexts formal, there are judgements for

- well-formed transition relations: $\bar{x} \vdash T$
- for well-formed specifications: $\bar{x} \vdash A$
- for well-formed specification contexts: $\Gamma \vdash \text{ok}$

For transition relations, $x_1, \dots, x_n \vdash T$ holds if all the free variables of T appear in x_1, \dots, x_n ; we omit the simple rules. Table 3 contains the rules for specifications and specification contexts. In case A is closed we may simply write A instead of $\vdash A$, and similarly for closed T .

Table 4 defines several transition relations that are used in the statement of the rules in the following subsection. The relation $T_{\text{res}}(e)$ states that the result of a computation is e and that the flat part of the store remains unchanged. While transition relations do not talk about the non-flat part of the store, the stored methods remain necessarily unchanged since the variant of the object calculus considered here has no method update. $T_{\text{obj}}(\mathbf{f}_i = x_i)$ describes the allocation of a new object in memory, which is initialised with field \mathbf{f}_i set to x_i , and whose location is returned as result. $T_{\text{upd}}(x, f, e)$ describes the effect on the store when updating field $x.f$. Note that in (Abadi and Leino, 2004) the relation T_{res} is called *Res* and T_{upd} is called *Update*. There is no abbreviation corresponding to T_{obj} .

Example 3.1. Table 5 shows a specification for the bank accounts of Example 2.1. Although we are using UML-like notation, these diagrams actually stand for individual objects, not classes – in fact there are no classes in the language. Observe how the

Table 5. An example of transition and result specifications

$T_{\text{deposit10}}(y)$	$\equiv \exists z. z = \text{sel}_{\text{pre}}(y, \text{balance})$ $\wedge T_{\text{upd}}(y, \text{balance}, z + 10)$	<pre> classDiagram class Manager { rate: Int accFactory } class AccFactory { manager create() } class Account { balance: Int deposit10() interest() } Manager --> AccFactory AccFactory --> Account AccFactory ..> Account </pre>
$T_{\text{interest}}(x, y)$	$\equiv \exists z. z = \text{sel}_{\text{pre}}(y, \text{balance})$ $\wedge \exists m. m = \text{sel}_{\text{pre}}(x, \text{manager})$ $\wedge \exists r. r = \text{sel}_{\text{pre}}(m, \text{rate})$ $\wedge T_{\text{upd}}(y, \text{balance}, z * r / 100)$	
$T_{\text{create}}(x)$	$\equiv T_{\text{obj}}(\text{balance} = 0)$	
$A_{\text{Account}}(x)$	$\equiv [\text{balance} : \text{Int},$ $\text{deposit10} : \zeta(y)[] :: T_{\text{deposit10}}(y),$ $\text{interest} : \zeta(y)[] :: T_{\text{interest}}(x, y)]$	
$A_{\text{AccFactory}}$	$\equiv [\text{manager} : [\text{rate} : \text{Int}],$ $\text{create} : \zeta(x)A_{\text{Account}}(x) :: T_{\text{create}}(x)]$	
A_{Manager}	$\equiv [\text{rate} : \text{Int},$ $\text{accFactory} : A_{\text{AccFactory}}]$	

specification T_{interest} depends not only on the self parameter y of the host object but also on the statically enclosing object x .

The result specifications $[]$ for the methods `deposit10` and `interest` in A_{Account} stand for the “empty” object. However, by the subspecification relation, defined below in Section 3.2, this specification is satisfied by any object. In particular, this is the case for both method implementations in Example 2.1 where the result is the object itself, according to the semantics of field update.

3.2. Abadi-Leino Logic

Abadi and Leino generalised the notion of subtypes to a form of *subspecifications*, $\bar{x} \vdash A <: A'$, that is defined inductively by $\bar{x} \vdash \text{Bool} <: \text{Bool}$ and the rule

$$\frac{\bar{x} \vdash A_i^{i=1\dots n+p} \quad \bar{x}, y_j \vdash B_j^{j=m+1\dots m+q} \quad \bar{x}, y_j \vdash T_j^{j=1\dots m+q} \quad \bar{x}, y_j \vdash T_j'^{j=1\dots m} \quad \bar{x}, y_j \vdash B_j <: B_j'^{j=1\dots m} \quad \vdash_{\text{fo}} T_j \rightarrow T_j'^{j=1\dots m}}{\bar{x} \vdash [f_i : A_i^{i=1\dots n+p}, m_j : \zeta(y_j)B_j :: T_j^{j=1\dots m+q}] <: [f_i : A_i^{i=1\dots n}, m_j : \zeta(y_j)B_j' :: T_j'^{j=1\dots m}]}$$

where $\vdash_{\text{fo}} \varphi$ denotes provability in first-order logic with equality (in the theory with axioms stating that `true`, `false` and all $f \in \mathcal{F}$ are distinct). Just as subtyping in the corresponding type system (Abadi and Cardelli, 1996), the subspecification relation is covariant along method specifications and transition relations, and invariant in field specifications. Observe that $\bar{x} \vdash A_1 <: A_2$ implies $\bar{x} \vdash A_i$ for $i = 1, 2$.

In the logic, judgements of the form $\Gamma \vdash a : A :: T$ can be derived, where Γ is a well-formed specification context, a is an object expression, A is a specification, and T is a transition relation. The rules guarantee that all the free variables of a , A and T appear in $[\Gamma]$. There is one rule for each syntactic form of the language, and additionally a subsumption rule which generalises the consequence rule of classical Hoare logic. The rules are given in Table 6.

Table 6. Inference rules of Abadi-Leino logic

SUBSUMPTION	$\frac{[\Gamma] \vdash A <: A' \quad \Gamma \vdash a:A::T \quad [\Gamma] \vdash A' \quad [\Gamma] \vdash T' \quad \vdash_{\text{fo}} T \rightarrow T'}{\Gamma \vdash a:A'::T'}$
VARIABLE	$\frac{\Gamma \vdash \text{ok} \quad x:A \text{ in } \Gamma}{\Gamma \vdash x:A::T_{\text{res}}(x)}$
BOOLEANS	$\frac{\Gamma \vdash \text{ok}}{\Gamma \vdash \text{false}:Book::T_{\text{res}}(\text{false})} \qquad \frac{\Gamma \vdash \text{ok}}{\Gamma \vdash \text{true}:Book::T_{\text{res}}(\text{true})}$
CONDITIONAL	$\frac{A[\text{true}/x] \equiv A_t[\text{true}/x] \text{ and } A[\text{false}/x] \equiv A_f[\text{false}/x] \quad T[\text{true}/x] \equiv T_t[\text{true}/x] \text{ and } T[\text{false}/x] \equiv T_f[\text{false}/x] \quad \Gamma \vdash x:Book::T_{\text{res}}(x) \quad \Gamma \vdash a:A_t::T_t \quad \Gamma \vdash b:A_f::T_f}{\Gamma \vdash \text{if } x \text{ then } a \text{ else } b:A::T}$
LET	$\frac{\Gamma \vdash a:A'::T' \quad \Gamma, x:A' \vdash b:B::T'' \quad [\Gamma] \vdash B \quad [\Gamma] \vdash T \quad \vdash_{\text{fo}} T'[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{post}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{post}}(\cdot), x/\text{result}] \quad \wedge T''[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{pre}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{pre}}(\cdot)] \rightarrow T}{\Gamma \vdash \text{let } x = a \text{ in } b:B::T}$
OBJECT CONSTRUCTION	$\frac{A \equiv [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}] \quad \Gamma \vdash x_i:A_i::T_{\text{res}}(x_i)^{i=1\dots n} \quad \Gamma, y_j:A \vdash b_j:B_j::T_j^{j=1\dots m}}{\Gamma \vdash [f_i = x_i^{i=1\dots n}, m_j = \varsigma(y_j)b_j^{j=1\dots m}]:A::T_{\text{obj}}(f_1=x_1 \dots f_n=x_n)}$
FIELD SELECTION	$\frac{\Gamma \vdash x:[f.A]::T_{\text{res}}(x)}{\Gamma \vdash x.f:A::T_{\text{res}}(\text{sel}_{\text{pre}}(x, f))}$
FIELD UPDATE	$\frac{A \equiv [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}] \quad \Gamma \vdash x:A::T_{\text{res}}(x) \quad \Gamma \vdash y:A_k::T_{\text{res}}(y) \quad 1 \leq k \leq n}{\Gamma \vdash x.f_k := y:A::T_{\text{upd}}(x, f_k, y)}$
METHOD INVOCATION	$\frac{\Gamma \vdash x:[m:\varsigma(y)A::T]::T_{\text{res}}(x)}{\Gamma \vdash x.m:A[x/y]::T[x/y]}$

As indicated before, one of the most interesting and powerful rules of the logic is the OBJECT INTRODUCTION rule,

$$\frac{A \equiv [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}] \quad \Gamma \vdash x_i:A_i::T_{\text{res}}(x_i)^{i=1\dots n} \quad \Gamma, y_j:A \vdash b_j:B_j::T_j^{j=1\dots m}}{\Gamma \vdash [f_i = x_i^{i=1\dots n}, m_j = \varsigma(y_j)b_j^{j=1\dots m}]:A::T_{\text{obj}}(f_i = x_i)^{i=1\dots n}}$$

In order to establish that the object satisfies specification A , when verifying the methods b_j we can *assume* that the self parameter y_j also satisfies A . Essentially, this causes the semantics of store specifications, introduced in the next section, to be defined by a *mixed-variant* recursion.

The rule for the LET case is somewhat unusual in that it introduces additional function and relation symbols to the signature, $\text{sel}_{\text{int}}(\cdot, \cdot)$ and $\text{alloc}_{\text{int}}(\cdot)$, to capture the intermediate state of the store in first-order logic. In the hypothesis, textual substitution of *function* and *predicate* symbols, respectively, is used to compose the first and second

transition relation: For instance,

$$\text{sel}_{\text{post}}(e_1, e_2)[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{post}}(\cdot, \cdot)] \equiv \text{sel}_{\text{int}}(e_1, e_2)$$

We omit the obvious general definition of this substitution operation. The side condition $[\Gamma] \vdash T$ ensures that the transition relation in the conclusion does not export this intermediate state.

Example 3.2. The proof rules of Abadi and Leino's logic can be used to derive the judgement

$$x:A_{\text{AccFactory}} \vdash \text{acc}(x) : A_{\text{Account}}(x) :: T_{\text{Obj}}(\text{balance} = 0) \quad (2)$$

for the *acc* object (cf. Example 2.1, 3.1). Using rule OBJECT CONSTRUCTION, (2) can be reduced to a trivial proof obligation for the field **balance**, a judgement for the method **deposit10**,

$$\Gamma \vdash \text{let } z=(y.\text{balance})+10 \text{ in } y.\text{balance}:=z : [] :: T_{\text{deposit10}}(y) \quad (3)$$

where Γ is the context $x:A_{\text{AccFactory}}, y:A_{\text{Account}}(x)$, and a similar judgement for the method **interest**. In turn, a proof of (3) involves showing

$$\Gamma \vdash (y.\text{balance})+10 : \text{Int} :: T_{\text{res}}(\text{sel}_{\text{pre}}(y, \text{balance}) + 10) \quad (4)$$

$$\Gamma, z:\text{Int} \vdash y.\text{balance}:=z : [] :: T_{\text{upd}}(y, \text{balance}, z) \quad (5)$$

for the constituents of the let expression, by an application of LET. These can be proved from the rules FIELD SELECTION and FIELD UPDATE, respectively.

As another example, the structural subspecification $\vdash A_{\text{Manager}} <: [\text{rate} : \text{Int}]$ and SUBSUMPTION can be used to prove

$$m:A_{\text{Manager}}, x:A_{\text{AccFactory}} \vdash x.\text{manager}:=m : A_{\text{AccFactory}} :: T_{\text{upd}}(x, \text{manager}, m)$$

when creating a reference to the manager object in the **manager** field of the factory object, as indicated by the diagram in Table 5.

3.3. Semantics of Specifications

Having recalled Abadi and Leino's logic, we next give a denotational semantics of specifications. In transition relations it is possible to quantify over field names, for examples of this see the transition relations in Table 4. We write $\text{Env}^* = \mathcal{V} \rightarrow_{\text{fin}} (\text{Val} \uplus \mathcal{F})$ when interpreting transition relations:

$$\llbracket \bar{x} \vdash T \rrbracket : \text{Env}^* \rightarrow \mathcal{P}(\text{St}_{\text{Val}} \times \text{Val} \times \text{St}_{\text{Val}})$$

This can be defined in a straightforward way, a few typical cases are given in Tables 7 and 8. Note that even though expressions may be undefined (for instance, because of referring to non-existent fields), the interpretation of transition relations is two-valued. Also observe that the meaning of a transition relation $\bar{x} \vdash T$ without free variables does not depend on the environment. Therefore we may omit the environment and simply write $\llbracket T \rrbracket$ for closed T .

Table 7. Semantics of expressions

$[\bar{x} \vdash e] : \text{Env}^* \rightarrow \text{StVal} \rightarrow \text{Val} \rightarrow \text{StVal} \rightarrow (\text{Val} \uplus \mathcal{F})$	
$[\bar{x} \vdash x]\rho\sigma v\sigma'$	$= \begin{cases} \rho(x) & \text{if } x \in \text{dom}(\rho) \\ \text{undefined} & \text{otherwise} \end{cases}$
$[\bar{x} \vdash \mathbf{f}]\rho\sigma v\sigma'$	$= \mathbf{f}$
$[\bar{x} \vdash \mathbf{result}]\rho\sigma v\sigma'$	$= v$
$[\bar{x} \vdash \mathbf{true}]\rho\sigma v\sigma'$	$= \mathbf{true}$
$[\bar{x} \vdash \mathbf{false}]\rho\sigma v\sigma'$	$= \mathbf{false}$
$[\bar{x} \vdash \text{sel}_{\text{pre}}(e_0, e_1)]\rho\sigma v\sigma'$	$= \begin{cases} \sigma.l.f & \text{if } [\bar{x} \vdash e_0]\rho\sigma v\sigma' = l \in \text{Loc} \text{ defined} \\ & \text{and } [\bar{x} \vdash e_1]\rho\sigma v\sigma' = f \in \mathcal{F} \text{ defined} \\ & \text{and } l \in \text{dom}(\sigma) \text{ and } f \in \text{dom}(\sigma.l) \\ \text{undefined} & \text{otherwise} \end{cases}$
$[\bar{x} \vdash \text{sel}_{\text{post}}(e_0, e_1)]\rho\sigma v\sigma'$	$= \begin{cases} \sigma'.l.f & \text{if } [\bar{x} \vdash e_0]\rho\sigma v\sigma' = l \in \text{Loc} \text{ defined} \\ & \text{and } [\bar{x} \vdash e_1]\rho\sigma v\sigma' = f \in \mathcal{F} \text{ defined} \\ & \text{and } l \in \text{dom}(\sigma') \text{ and } f \in \text{dom}(\sigma'.l) \\ \text{undefined} & \text{otherwise} \end{cases}$

Table 8. Semantics of transition relations

$[\bar{x} \vdash T] : \text{Env}^* \rightarrow \mathcal{P}(\text{StVal} \times \text{Val} \times \text{StVal})$	
$(\sigma, v, \sigma') \in [\bar{x} \vdash e_0 = e_1]\rho$	$\iff \begin{cases} \text{both } [\bar{x} \vdash e_0]\rho\sigma v\sigma' \text{ and } [\bar{x} \vdash e_1]\rho\sigma v\sigma' \text{ are defined} \\ \text{and equal, or both undefined} \end{cases}$
$(\sigma, v, \sigma') \in [\bar{x} \vdash \text{alloc}_{\text{pre}}(e)]\rho$	$\iff [\bar{x} \vdash e]\rho\sigma v\sigma' \downarrow \wedge [\bar{x} \vdash e]\rho\sigma v\sigma' \in \text{dom}(\sigma)$
$(\sigma, v, \sigma') \in [\bar{x} \vdash \text{alloc}_{\text{post}}(e)]\rho$	$\iff [\bar{x} \vdash e]\rho\sigma v\sigma' \downarrow \wedge [\bar{x} \vdash e]\rho\sigma v\sigma' \in \text{dom}(\sigma')$
$(\sigma, v, \sigma') \in [\bar{x} \vdash \neg T]\rho$	$\iff (\sigma, v, \sigma') \notin [\bar{x} \vdash T]\rho$
$(\sigma, v, \sigma') \in [\bar{x} \vdash T_0 \wedge T_1]\rho$	$\iff (\sigma, v, \sigma') \in [\bar{x} \vdash T_0]\rho \cap [\bar{x} \vdash T_1]\rho$
$(\sigma, v, \sigma') \in [\bar{x} \vdash \forall x. T]\rho$	$\iff \text{for all } u \in \text{Val} \uplus \mathcal{F}. (\sigma, v, \sigma') \in [\bar{x}, x \vdash T]\rho[x := u]$

Table 9. Semantics of specifications

$[\bar{x} \vdash A] : \text{Env} \rightarrow \mathcal{P}(\text{Val} \times \text{St})$	
$[\bar{x} \vdash \text{Bool}]\rho$	$= \text{BVal} \times \text{St}$
$[\bar{x} \vdash [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]]\rho$	$= \left\{ (l, \sigma) \in \text{Loc} \times \text{St} \left \begin{array}{l} \text{(F)} \quad \forall 1 \leq i \leq n. (\sigma.l.f_i, \sigma) \in [\bar{x} \vdash A_i]\rho \\ \text{(M)} \quad \forall 1 \leq j \leq m. \text{ if } \sigma.l.m_j(l, \sigma) = (v, \sigma') \downarrow \\ \text{then } (v, \sigma') \in [\bar{x}, y_j \vdash B_j]\rho[y_j := l] \\ \text{and } (\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in [\bar{x}, y_j \vdash T_j]\rho[y_j := l] \end{array} \right. \right\}$

Remark 3.3. We think it would be clearer to use a multi-sorted logic, with different quantifiers ranging over locations, basic values and field names, respectively, but decided to keep close to the original presentation of Abadi and Leino’s logic.

An object specification $\bar{x} \vdash A$ gives rise to a predicate that depends on values for the free variables \bar{x} . However, since the underlying logic in the transition relations is untyped, the types of the free variables are not relevant. The interpretation of object specifications $\bar{x} \vdash A$,

$$\llbracket \bar{x} \vdash A \rrbracket : \text{Env} \rightarrow \mathcal{P}(\text{Val} \times \text{St})$$

is given in Table 9.

We begin with two simple observations about the interpretation.

Lemma 3.4. For all specifications $\bar{x} \vdash A$, store $\sigma \in \text{St}$ and environments ρ we have $(\text{error}, \sigma) \notin \llbracket \bar{x} \vdash A \rrbracket \rho$.

Proof. Immediate from the definition of $\llbracket \bar{x} \vdash A \rrbracket \rho$. □

This observation will be used to obtain soundness of the proof system, in the sense of “well-typed (or rather, *verified*) programs do not raise errors”.

Lemma 3.5 (Soundness of Subspecification). Suppose $\bar{x} \vdash A <: B$. Then, for all environments ρ , $\llbracket \bar{x} \vdash A \rrbracket \rho \subseteq \llbracket \bar{x} \vdash B \rrbracket \rho$ for values \bar{v} .

Proof. This follows by induction on the derivation of $\bar{x} \vdash A <: B$. The cases for reflexivity and transitivity are immediate. For the case where both A and B are object specifications we need a similar lemma for transition relations:

If $\bar{x} \vdash T$ and $\bar{x} \vdash T'$ then

$$\vdash_{\text{fo}} T \rightarrow T' \implies \llbracket \bar{x} \vdash T \rrbracket \rho \subseteq \llbracket \bar{x} \vdash T' \rrbracket \rho \quad (6)$$

for all $\rho \in \text{Env}^*$. However, (6) follows immediately since \vdash_{fo} is sound for all models of first-order logic. □

4. Store Specifications

Object specifications are not sufficient. This is a phenomenon of languages with higher-order store well known from subject reduction and type soundness proofs in both operational and denotational settings (for instance see (Abadi and Cardelli, 1996, Chap. 11) and the references therein, and (Levy, 2002), respectively). Since statements may call subprograms residing in the store, the store has to be checked as well. However, it may contain loops and therefore induction on the reachable part of the store is unavailable.

The standard remedy – also used in (Abadi and Leino, 2004) – is to relativise the typing judgement such that it only needs to hold for “verified” stores. In other words, judgements are interpreted with respect to *store specifications*. A store specification Σ assigns a specification to each location in a store:

$$\Sigma \equiv l_1:A_1, \dots, l_n:A_n$$

When an object is created, the specification assigned to it at the time of creation is included in the store specification. This leads to a natural notion of *store specification extension*.

In this section we will interpret such store specifications using the techniques from (Reus and Streicher, 2004). Since the denotations of a store specification will rely on mixed-variant recursion, we were not able to define a semantic notion of subspecification for stores. However, the logic of Abadi and Leino makes essential use of subspecifications.

We get around this problem by only using a subset relationship on denotations of object specifications. In object specifications there is no contravariant occurrence of store as the semantics of objects is with respect to one fixed store (cf. Table 9).

Unfortunately, we are restricted by the logic's requirement that verified statements never break the validity of store specifications. Suppose y denotes an object in σ satisfying a specification B . For a field update $\sigma.l.f := y$ to preserve a specification $l : A$ where $A <: [f : B]$, the location l must be in the set

$$\{l \in \text{Loc} \mid \Sigma.l \text{ is } A' \text{ and } \vdash A' <: A\} \quad (7)$$

which ensures that A and A' both have a component named f , of type B . Since the semantic interpretation of the subspecification relation as set containment cannot reflect this invariance, preservation can *not* be guaranteed for locations in the (semantically more appealing) set

$$\{l \in \text{dom}(\sigma) \mid (l, \sigma) \in \llbracket A \rrbracket\}$$

Therefore we were forced to use the former set (7) for the interpretation of A in the semantics of store specifications.

4.1. Result Specifications, Store Specifications and a Tentative Semantics

A store specification Σ assigns *closed* specifications $\vdash A$ to (a finite set of) locations:

Definition 4.1 (Store Specification). A record $\Sigma \in \text{Rec}_{\text{Loc}}(\text{Spec})$ is a *store specification* if for all $l \in \text{dom}(\Sigma)$, $\Sigma.l$ is a closed object specification. Let StSpec denote the set of store specifications.

Because we focus on closed specifications in the following, we need a way to turn the components B_j of a specification $[f_i : A_i^{i=1 \dots n}, m_j : \varsigma(y_j)B_j :: T_j^{j=1 \dots m}]$ (which in general will depend on the self parameter y_j) into closed specifications. We do this by extending the syntax of expressions with locations: There is one symbol \underline{l} for each $l \in \text{Loc}$, and define $\llbracket \bar{x} \vdash \underline{l} \rrbracket \rho = l$ (cf. Table 7). Similarly, we set $\underline{\text{true}} = \text{true}$ and $\underline{\text{false}} = \text{false}$. When clear from context we will simply write v in place of \underline{v} .

Further we write $A[\rho/\bar{x}]$ (and $A[\rho/\Gamma]$, resp.) for the simultaneous substitution of all $x \in \bar{x}$ ($x \in \Gamma$, respectively) in A by $\underline{\rho(x)}$. Then we can prove the following substitution lemma.

Lemma 4.2 (Substitution Lemma). Suppose ρ is an environment, $\bar{x} \vdash T$ is a transition relation and $\bar{y} \vdash A$ and $\bar{y} \vdash A'$ are specifications. Then

- $T[\rho/\bar{x}]$ is well-formed, and $\llbracket T[\rho/\bar{x}] \rrbracket = \llbracket \bar{x} \vdash T \rrbracket \rho$
- $A[\rho/\bar{y}]$ is well-formed, and $\llbracket A[\rho/\bar{y}] \rrbracket = \llbracket \bar{y} \vdash A \rrbracket \rho$
- if $\bar{y} \vdash A <: A'$ then $\vdash A[\rho/\bar{y}] <: A'[\rho/\bar{y}]$

Proof. The first part is by induction on T , the second by induction on A and the last by induction on the derivation of $\bar{y} \vdash A <: A'$. \square

Definition 4.3 (Store Specification Extension). Let $\Sigma, \Sigma' \in StSpec$ be store specifications. Σ' *extends* Σ , written $\Sigma' \succ \Sigma$, if $\text{dom}(\Sigma) \subseteq \text{dom}(\Sigma')$ and $\Sigma.l = \Sigma'.l$ for all $l \in \text{dom}(\Sigma)$.

Note that \succ is reflexive and transitive. We can then abstract away from particular stores $\sigma \in \mathbf{St}$, and interpret closed result specifications $\vdash A$ with respect to such store specifications:

Definition 4.4 (Object Specifications). Suppose $\Sigma \in StSpec$ is a store specification. For closed $\vdash A$ let $\|A\|_\Sigma \subseteq \mathbf{Val}$ be defined by

$$\begin{aligned} \|Bool\|_\Sigma &= \mathbf{BVal} \\ \|B\|_\Sigma &= \{l \in \mathbf{Loc} \mid \vdash \Sigma.l <: B\} \end{aligned}$$

where $B \equiv [f_i: A_i^{i=1\dots n}, m_j: \zeta(y_j)B_j::T_j^{j=1\dots m}]$ and $\vdash B$. We extend this definition to specification contexts $\|\Gamma\|_\Sigma \subseteq \mathbf{Env}$ in the natural way:

$$\begin{aligned} \rho \in \|\emptyset\|_\Sigma &\iff \text{always} \\ \rho \in \|\Gamma, x:A\|_\Sigma &\iff \rho \in \|\Gamma\|_\Sigma \quad \wedge \quad \rho(x) \in \|A[\rho/\Gamma]\|_\Sigma \end{aligned}$$

Observe that for all A , if $\Sigma' \succ \Sigma$ then $\|A\|_\Sigma \subseteq \|A\|_{\Sigma'}$. We obtain the following lemma about *context extensions*.

Lemma 4.5 (Context Extension). If $\rho \in \|\Gamma\|_\Sigma$ and $\Gamma, x:A \vdash \text{ok}$ and $v \in \|A[\rho/\Gamma]\|_\Sigma$ then $\rho[x := v] \in \|\Gamma, x:A\|_\Sigma$.

Proof. The result follows immediately from the definition once we show $\rho[x := v] \in \|\Gamma\|_\Sigma$. This can be seen to hold since $x \notin \text{dom}(\Gamma)$, hence for all $y:B$ in Γ we know that x is not free in B and we must have $B[\rho[x := v]/\Gamma] \equiv B[\rho/\Gamma]$. \square

The semantics of a store specification $\Sigma = l_1:A_1, \dots, l_n:A_n$ as a predicate over stores in \mathbf{St} must be more sophisticated than one might think at first sight. In particular, it is not enough to stipulate that $\sigma \in \llbracket \Sigma \rrbracket$ iff $(\sigma.l_i, \sigma) \in \llbracket A_i \rrbracket$ for all $1 \leq i \leq n$, for then we could not infer anything about stores that are derived from σ by *updating* or *allocating additional objects*. To show that Σ is invariant throughout the execution of a program, a key lemma for the soundness theorem, the assumption $\sigma \in \llbracket \Sigma \rrbracket$ is not sufficiently strong to conclude that e.g. $\sigma[l := \sigma.l[f := 0]]$ or $\sigma[l_{new} := o]$ still fulfil $\llbracket \Sigma \rrbracket$.

This deficiency explains the need for a mixed variant recursive definition of the semantics of $\llbracket \Sigma \rrbracket$, with a universal quantification over *arbitrary argument stores* σ' assumed to already fulfil the store specification we are defining. Thus, if the equivalence in Table 10 is taken as the defining property of $\llbracket \Sigma \rrbracket$, this quantification in (M) provides a handle to the update problem. Furthermore, using the extension relation of store specifications allows

Table 10. Store specifications, first (and incorrect) attempt

$\sigma \in [\Sigma]$	\iff	$\forall l \in \text{dom}(\Sigma)$ where $\Sigma.l \equiv [f_i : A_i^{i=1\dots n}, m_j : \varsigma(y_j)B_j :: T_j^{j=1\dots m}] :$
	(F)	$\forall 1 \leq i \leq n. \sigma.l.f_i \in \ A_i\ _\Sigma;$ and
	(M)	$\forall 1 \leq j \leq m \forall \Sigma' \succ \Sigma \forall \sigma', \sigma'' \in \text{St} \forall l' \in \text{Loc} \forall v \in \text{Val}.$ if $l' \in \ \Sigma.l\ _{\Sigma'} \wedge \sigma' \in [\Sigma'] \wedge \sigma.l.m_j(l', \sigma') = (v, \sigma'')$ then
	(M1)	$(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in [T_j[l'/y_j]]$ and
	(M2)	$\exists \Sigma'' \in \text{StSpec}. \Sigma'' \succ \Sigma' \wedge \sigma'' \in [\Sigma'']$ and
	(M3)	$v \in \ B_j[l'/y_j]\ _{\Sigma''}$

Table 11. Functional for store specifications, first (and incorrect) attempt

$\sigma \in \Phi(Y, X)_\Sigma$	\iff	$\forall l \in \text{dom}(\Sigma)$ where $\Sigma.l \equiv [f_i : A_i^{i=1\dots n}, m_j : \varsigma(y_j)B_j :: T_j^{j=1\dots m}] :$
	(F)	$\forall 1 \leq i \leq n. \sigma.l.f_i \in \ A_i\ _\Sigma;$ and
	(M)	$\forall 1 \leq j \leq m \forall \Sigma' \succ \Sigma \forall \sigma', \sigma'' \in \text{St} \forall l' \in \text{Loc} \forall v \in \text{Val}.$ if $l' \in \ \Sigma.l\ _{\Sigma'} \wedge \sigma' \in Y_{\Sigma'} \wedge \sigma.l.m_j(l', \sigma') = (v, \sigma'')$ then
	(M1)	$(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in [T_j[l'/y_j]]$ and
	(M2)	$\exists \Sigma'' \in \text{StSpec}. \Sigma'' \succ \Sigma' \wedge \sigma'' \in X_{\Sigma''}$ and
	(M3)	$v \in \ B_j[l'/y_j]\ _{\Sigma''}$

us to address the issues with allocation: The universal quantification over extensions Σ' of Σ in (M) accounts for the specifications of objects allocated between time of definition and time of call of methods. The existential quantification over extensions Σ'' of Σ in (M2) and (M3) provides for objects allocated by the method. In particular, since the result of a method call may be a freshly allocated object it is not sufficient to simply use Σ' in (M2) and (M3).

This semantic structure also appears in models for many other languages with dynamic allocation (Levy, 2002; Levy, 2004; Reddy and Yang, 2004; Stark, 1998; Banerjee and Naumann, 2005; Moggi, 1990). It is particularly obvious in those models explicitly constructed in terms of possible worlds. Indeed, we may view $\|A\|$ as a functor from the partial order category (StSpec, \succ) to the category of subsets of Val ordered by set inclusion, for every specification A .

The standard approach to obtain predicates defined by a mixed-variant recursion proceeds as follows. Let $\mathcal{R} = \mathcal{P}(\text{St})^{\text{StSpec}}$ denote the collection of predicates on St , indexed by store specifications, and define a functional $\Phi : \mathcal{R}^{\text{op}} \times \mathcal{R} \rightarrow \mathcal{R}$ according to Table 11. We would then like to write $[\Sigma]$ for $\text{fix}(\Phi)_\Sigma$. Unfortunately, there is a problem with the definition of $[\Sigma]$ as $\text{fix}(\Phi)_\Sigma$, which we discuss next.

4.2. On the Existence of Store Specifications

The contravariant occurrence of Y in case (M) of the “definition” of Φ above is forced by the premise of the object construction rule in the Abadi-Leino logic. It states that, in order to prove that specification A holds for a new object, one can assume that the self object in methods already fulfils the specification A . It is this contravariance, in turn, that calls for some advanced domain theory to show that the fixpoint of Φ does actually exist.

Unfortunately, the usual techniques (Pitts, 1996; Reus and Streicher, 2004) for establishing the existence of such predicates involving a mixed-variance recursion (suitably extended to *families* of predicates) do not apply: They require the functional Φ of Table 11 to map *admissible predicates* to *admissible predicates*. Due to the existential quantification in cases (M2) and (M3), ranging over extensions of Σ' , this property fails here. To see this failure, a counterexample is sketched in the remainder of this subsection, which the reader may wish to skip.

Essentially, the counterexample relies on the fact that we are dealing with *families* $X = (X_\Sigma)_{\Sigma \in StSpec}$ of predicates. Due to the existential quantification over the indices $\Sigma \in StSpec$ it is possible to pick *different* Σ_i for each element of an ω -chain $f_0 \sqsubseteq f_1 \sqsubseteq f_2 \sqsubseteq \dots$ so that $f_i(x) \in X_{\Sigma_i}$, i.e., the chain need not be in line with the family $(X_\Sigma)_\Sigma$. Thus, in general there need not be any $\Sigma^\circ \in StSpec$ such that $f(x) \in X_{\Sigma^\circ}$ holds for the lub $f = \sqcup_i f_i$, even under the assumption that each X_Σ is closed under taking least upper bounds.

In more detail, let

$$\Sigma = l_0 : [\mathfrak{m}_0 : \varsigma(x)[\mathfrak{m}_1 : \varsigma(y)]::True]::True]$$

which, informally, describes a store with a single object at location l_0 containing a method \mathfrak{m}_0 . In case a call of this method converges it returns an object satisfying $[\mathfrak{m}_1 : \varsigma(y)]::True$ (which is not much of a restriction). However, this resulting object has to be allocated in the store, and so a proper extension of the original store specification Σ has to be found.

Next, for $i \in \mathbb{N}$ let A_i be the object specification defined inductively by

$$\begin{aligned} A_0 &= [\mathfrak{m}_1 : \varsigma(y)]::False] \\ A_{i+1} &= [\mathfrak{m}_1 : \varsigma(y)A_i::True] \end{aligned}$$

In particular, this means that the method \mathfrak{m}_1 of objects satisfying A_0 *must* diverge. The method \mathfrak{m}_1 of an object satisfying A_i returns an object satisfying A_{i-1} . Hence, for such objects x , it is possible to have method calls $x.\mathfrak{m}_1.\mathfrak{m}_1 \dots \mathfrak{m}_1$ at most i times, of which the i -th call must necessarily diverge (the others may or may not terminate).

The example below uses the fact that we can construct an ascending chain of objects for which the first $i-1$ calls indeed terminate, and which therefore do *not* satisfy A_{i-1} . Then, the limit of this chain is an object x for which an arbitrary number of calls $x.\mathfrak{m}_1.\mathfrak{m}_1 \dots \mathfrak{m}_1$ terminates, and which therefore does not satisfy *any* of the A_i : Set $\Sigma''_i = \Sigma, l : A_i$ and let $\underline{\sigma} \in \llbracket \Sigma \rrbracket$ denote some store satisfying Σ according to the tentative definition above. Moreover, define

$$\sigma_i = \{l_0 = \{\mathfrak{m}_0 = \lambda_.(l, \underline{\sigma} + \sigma''_i)\}\}$$

where $\sigma''_0 = \{l = \{\mathfrak{m}_1 = \lambda_.\perp\}\}$ and $\sigma''_{i+1} = \{l = \{\mathfrak{m}_1 = \lambda_.(l, \underline{\sigma} + \sigma''_i)\}\}$, and let

$\sigma = \sqcup_i \sigma_i$. Finally, define (indexed) relations $X, Y \in \mathcal{R}$ by

$$\begin{aligned} X_{\hat{\Sigma}} &= \begin{cases} \{\underline{\sigma} + \sigma_i''\} & \text{if } \exists i \in \mathbb{N}. \hat{\Sigma} \equiv \Sigma_i'' \\ \emptyset & \text{otherwise} \end{cases} \\ Y_{\hat{\Sigma}} &= \begin{cases} \{\underline{\sigma}\} & \text{if } \hat{\Sigma} \equiv \Sigma \\ \emptyset & \text{otherwise} \end{cases} \end{aligned}$$

By construction, both X and Y are admissible in every component $\hat{\Sigma}$. By induction one obtains $\sigma_0'' \sqsubseteq \sigma_1'' \sqsubseteq \dots$, therefore $\sigma_0 \sqsubseteq \sigma_1 \sqsubseteq \dots$ in $\Phi(Y, X)_{\Sigma} \subseteq \mathbf{St}$. Hence we must show $\sigma \in \Phi(Y, X)_{\Sigma}$. But this is not the case, since it would entail, by (M2) and

$$\sigma.l_0.m_0(l, \underline{\sigma}) = \sqcup_i \sigma_i.l_0.m_0(l, \underline{\sigma}) = (l, \underline{\sigma} + \sqcup_i \sigma_i'')$$

that there exists $\Sigma'' \succ \Sigma$ such that $\underline{\sigma} + \sqcup_i \sigma_i'' \in X_{\Sigma''}$. Clearly this does not hold: $\underline{\sigma} + \sqcup_i \sigma_i''$ is *strictly* above every $\underline{\sigma} + \sigma_i''$ and therefore not in any of the $X_{\Sigma_i''}$. Hence, by choice of X , there is no store specification $\Sigma'' \succ \Sigma$ such that $\underline{\sigma} + \sigma_i'' \in X_{\Sigma''}$. This shows that $\Phi(Y, X)_{\Sigma}$ is not necessarily admissible, even if X (and also Y) is.

4.3. A Refined Semantics of Store Specifications

We refine the definition of store predicates by replacing the existential quantifier in condition (M2) of the functional Φ from Table 11 by a choice function, as follows: We call the elements of the (recursively defined) domain

$$\phi \in \text{RSF} = \text{Rec}_{\text{Loc}}(\text{Rec}_{\mathcal{M}}(\mathbf{St} \times \text{RSF} \times \text{StSpec} \rightarrow \text{StSpec} \times \text{RSF})) \quad (8)$$

(records of) *choice functions*. The intuition is that, given a store $\sigma \in \llbracket \Sigma \rrbracket$ and some extension $\Sigma' \succ \Sigma$, if $\sigma' \in \llbracket \Sigma' \rrbracket$ with choice function ϕ' and the method invocation $\sigma.l.m(\sigma')$ terminates, then $\phi.l.m(\sigma', \phi', \Sigma') = (\Sigma'', \phi'')$ yields a store specification $\Sigma'' \succ \Sigma'$ such that $\sigma'' \in \llbracket \Sigma'' \rrbracket$ (and ϕ'' is a choice function for the extension Σ'' of Σ). This is again an abstraction of the actual store σ , this time abstracting the *dynamic effects* of methods with respect to allocation, on the level of store specifications. Note that the argument store σ' is needed in general to determine the resulting extension of the specification, since allocation behaviour may depend on the actual values of fields.

We use the domain RSF of choice functions explicitly in the interpretation of store specifications below. This has the effect of constraining the existential quantifier to work *uniformly* on the elements of increasing chains, hence precluding the counter-example to admissibility of the previous subsection.

Definition 4.6 (Store Predicate, Revisited). Let $\mathcal{S} = \mathcal{P}(\mathbf{St} \times \text{RSF})^{\text{StSpec}}$ denote the collection of families of subsets of $\mathbf{St} \times \text{RSF}$, indexed by store specifications. Table 12 defines a functional $\Phi : \mathcal{S}^{op} \times \mathcal{S} \rightarrow \mathcal{S}$; we write $\sigma \in \llbracket \Sigma \rrbracket$ if there is some $\phi \in \text{RSF}$ such that $(\sigma, \phi) \in \text{fix}(\Phi)_{\Sigma}$.

Lemma 4.7 (Existence). Functional Φ , defined in Definition 4.6, does have a unique fixed point.

Table 12. Store specifications

$(\sigma, \phi) \in \Phi(Y, X)_\Sigma$	\iff	(DOM1) $\text{dom}(\Sigma) = \text{dom}(\phi)$; and (DOM2) $\forall l \in \text{dom}(\Sigma)$. if $\text{dom}(\Sigma.l) \equiv [f_i: A_i^{i=1\dots n}, m_j: \zeta(y_j)B_j::T_j^{j=1\dots m}]$ then $\text{dom}(\phi.l) = \{m_j\}_{j=1\dots m}$; and $\forall l \in \text{dom}(\Sigma)$ where $\Sigma.l \equiv [f_i: A_i^{i=1\dots n}, m_j: \zeta(y_j)B_j::T_j^{j=1\dots m}]$: (F) $\forall 1 \leq i \leq n$. $\sigma.l.f_i \in \ A_i\ _\Sigma$; and (M) $\forall 1 \leq j \leq m$ $\forall \Sigma' \succcurlyeq \Sigma \forall \sigma', \sigma'' \in \text{St} \forall \phi' \in \text{RSF} \forall l' \in \text{Loc} \forall v \in \text{Val}$. if $l' \in \ \Sigma.l\ _{\Sigma'}$ \wedge $(\sigma', \phi') \in Y_{\Sigma'}$ \wedge $\sigma.l.m_j(l', \sigma') = (v, \sigma'')$ then $\exists \Sigma'' \succcurlyeq \Sigma' \exists \phi'' \in \text{RSF}$. $\phi.l.m_j(l', \sigma', \phi', \Sigma') = (\Sigma'', \phi'')$ and (M1) $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in [T_j[l'/y_j]]$; and (M2) $(\sigma'', \phi'') \in X_{\Sigma''}$; and (M3) $v \in \ B_j[l'/y_j]\ _{\Sigma''}$
--	--------	---

Proof. Firstly, one shows that Φ is monotonic and maps admissible predicates to admissible predicates, in the sense that for all X and Y ,

$$\begin{aligned} \forall \Sigma \in \text{StSpec}. X_\Sigma \subseteq \text{St} \times \text{RSF} \text{ admissible} \\ \implies \forall \Sigma \in \text{StSpec}. \Phi(Y, X)_\Sigma \subseteq \text{St} \times \text{RSF} \text{ admissible} \end{aligned} \quad (9)$$

Indeed, if $(\sigma_0, \phi_0) \sqsubseteq (\sigma_1, \phi_1) \sqsubseteq \dots$ is a chain in $\Phi(Y, X)_\Sigma$, then $\sigma_0 \sqsubseteq \sigma_1 \sqsubseteq \dots$ in St and $\phi_0 \sqsubseteq \phi_1 \sqsubseteq \dots$ in RSF . Let $\sigma = \sqcup_k \sigma_k$ and $\phi = \sqcup_k \phi_k$ (so $(\sigma, \phi) = \sqcup_k (\sigma_k, \phi_k)$), we show $(\sigma, \phi) \in \Phi(Y, X)_\Sigma$ under the assumption that $X_{\Sigma'}$ is admissible for all $\Sigma' \in \text{StSpec}$.

Clearly conditions (DOM1) and (DOM2) of Definition 4.6 are satisfied. As for (F) and (M), suppose $l \in \text{dom}(\Sigma)$ with $\Sigma.l = [f_i: A_i^{i=1\dots n}, m_j: \zeta(y_j)B_j::T_j^{j=1\dots m}]$. Since, for all $1 \leq i \leq n$,

$$\sigma_0.l.f_i = \sigma_1.l.f_i = \dots = \sigma.l.f_i$$

we obtain $\sigma.l.f_i \in \|A_i\|_\Sigma$ by assumption $(\sigma_0, \phi_0) \in \Phi(Y, X)_\Sigma$, showing (F). To prove (M), suppose $\Sigma' \succcurlyeq \Sigma$, $(\sigma', \phi') \in Y_{\Sigma'}$ and $\sigma.l.m_j(\sigma') = (v, \sigma'') \downarrow$ for some $v \in \text{Val}$ and $\sigma'' \in \text{St}$. By definition of σ as $\sqcup_k \sigma_k$ and continuity of $\sigma.l.m_j$, there must be $\sigma''_k \in \text{St}$ and $\sigma_k.l.m_j(\sigma') = (v, \sigma''_k) \downarrow$ for sufficiently large k , and

$$(v, \sigma'') = \sqcup_k \sigma_k.l.m_j(\sigma') = \sqcup_k (v, \sigma''_k)$$

By assumption $(\sigma_k, \phi_k) \in \Phi(Y, X)_\Sigma$, hence for all sufficiently large k , $\phi_k.l.m_j(\sigma', \phi', \Sigma') = (\Sigma''_k, \phi''_k)$ with $\Sigma''_k \succcurlyeq \Sigma'$ and

- $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma''_k)) \in [T_j[l/y_j]]$; and
- $(\sigma''_k, \phi''_k) \in X_{\Sigma''_k}$; and
- $v \in \|B_j[l/y_j]\|_{\Sigma''_k}$

Since $\pi_{\text{Val}}(\sigma''_k) = \pi_{\text{Val}}(\sigma'')$, condition (M1) follows. The discrete order on Spec entails $\Sigma''_k \equiv \Sigma''_{k+1} \equiv \dots$, hence, $\phi(\sigma', \phi', \Sigma') = \sqcup (\Sigma''_k, \phi''_k) = (\Sigma'', \sqcup_k \phi''_k)$ with $\Sigma'' \equiv \Sigma''_k \equiv \Sigma''_{k+1} \equiv \dots$, and clearly (M3) is satisfied. By assumption $X_{\Sigma''}$ is admissible therefore also condition (M2) holds as required, i.e., $(\sigma'', \phi'') = \sqcup (\sigma''_k, \phi''_k) \in X_{\Sigma''}$. This proves claim (9).

Next, define for all admissible $X, X' \in \mathcal{S}$ and $e = (e_1, e_2) \in [\mathbf{St} \multimap \mathbf{St}] \times [\mathbf{RSF} \multimap \mathbf{RSF}]$:

$$\begin{aligned} e : X \subset X' &\iff \forall \Sigma \in \mathit{StSpec} \ \forall \sigma \in \mathbf{St} \ \forall \phi \in \mathbf{RSF}. \\ &(\sigma, \phi) \in X_\Sigma \wedge (e_1(\sigma) \downarrow \vee e_2(\phi) \downarrow) \\ &\implies e_1(\sigma) \downarrow \wedge e_2(\phi) \downarrow \wedge (e_1(\sigma), e_2(\phi)) \in X'_\Sigma \end{aligned}$$

such that $e : X \subset X'$ states that e maps pairs of stores and choice functions that are in X_Σ to pairs of stores and choice functions that are in corresponding component X'_Σ of X' . Let F_{Store} be the locally continuous, mixed-variant functor associated with the domain equations (1), for which $F_{Store}(\mathbf{St}, \mathbf{St}) = \mathbf{St}$, and consider the locally continuous functor $F_{\mathbf{St}, \mathbf{RSF}}(R, S) : (\mathbf{pCpo} \times \mathbf{pCpo})^{op} \times \mathbf{pCpo} \times \mathbf{pCpo} \rightarrow \mathbf{pCpo} \times \mathbf{pCpo}$

$$\begin{aligned} F_{\mathbf{St}, \mathbf{RSF}}(R, S) = &\langle F_{Store}(\Pi_1(R), \Pi_1(S)), \\ &\mathbf{Rec}_{\mathbf{Loc}}(\mathbf{Rec}_{\mathcal{M}}(\Pi_1(R) \times \Pi_2(R) \times \mathit{StSpec} \multimap \mathit{StSpec} \times \Pi_2(S))) \rangle \end{aligned}$$

where Π_i is the projection to the i -th component. Hence $(\mathbf{St}, \mathbf{RSF})$ is the minimal invariant for $F_{\mathbf{St}, \mathbf{RSF}}$. In the following, we write $F_{\mathbf{St}}$ for the functor $\Pi_1 \circ F_{\mathbf{St}, \mathbf{RSF}}$ and $F_{\mathbf{RSF}}$ for $\Pi_2 \circ F_{\mathbf{St}, \mathbf{RSF}}$. By the results of (Pitts, 1996) it only remains to be shown that

$$e : X \subset X' \wedge e : Y' \subset Y \implies F_{\mathbf{St}, \mathbf{RSF}}(e, e) : \Phi(Y, X) \subset \Phi(Y', X') \quad (\dagger)$$

for all $X, Y, X', Y' \in \mathcal{S}$ and $e = (e_1, e_2)$ with $e_1 \sqsubseteq id_{\mathbf{St}}$ and $e_2 \sqsubseteq id_{\mathbf{RSF}}$ which follows from a similar line of reasoning as in (Reus and Streicher, 2004): Suppose $e = (e_1, e_2)$ such that $e_1 \sqsubseteq id_{\mathbf{St}}$, $e_2 \sqsubseteq id_{\mathbf{RSF}}$,

$$e : X \subset X' \quad \wedge \quad e : Y' \subset Y \quad (10)$$

for some $X, Y, X', Y' \in \mathcal{S}$. Assume $(\sigma, \phi) \in \Phi(Y, X)_\Sigma$. We must show $F_{\mathbf{St}, \mathbf{RSF}}(e, e)(\sigma, \phi) \in \Phi(Y', X')_\Sigma$ to prove (\dagger) . Recall that

$$F_{\mathbf{St}}(e, e)(\sigma, \phi).lf = \sigma.lf \quad (11a)$$

$$F_{\mathbf{St}}(e, e)(\sigma, \phi).l.m(\sigma') = (id_{\mathbf{Val}} \times e_1)(\sigma.l.m(e_1(\sigma'))) \quad (11b)$$

$$F_{\mathbf{RSF}}(e, e)(\sigma, \phi).l.m(\sigma', \phi', \Sigma') = (id_{\mathit{StSpec}} \times e_2)(\phi.l.m(e_1(\sigma'), e_2(\phi'), \Sigma')) \quad (11c)$$

for all $f \in \mathcal{F}$ and $m \in \mathcal{M}$. In particular, conditions (DOM1) and (DOM2) of Definition 4.6 are immediately seen to be satisfied for $F_{\mathbf{St}, \mathbf{RSF}}(e, e)(\sigma, \phi)$.

To show (F) and (M) let $l \in \mathbf{dom}(\Sigma)$, and $\Sigma.l \equiv [f_i : A_i^{i=1 \dots n}, m_j : \varsigma(y_j)B_j :: T_j^{j=1 \dots m}]$. From $(\sigma, \phi) \in \Phi(Y, X)_\Sigma$ and (11a) we obtain for all $1 \leq i \leq n$

$$(F) \quad F_{\mathbf{St}}(e, e)(\sigma, \phi).lf_i \in \|A_i\|_\Sigma$$

It remains to check conditions (M1)–(M3) of Definition 4.6. Let $1 \leq j \leq m$. Suppose $\Sigma' \succ \Sigma$, $\phi' \in \mathbf{RSF}$ and $\sigma' \in \mathbf{St}$ with $(\sigma', \phi') \in Y'_\Sigma$, and such that $F_{\mathbf{St}}(e, e)(\sigma, \phi).l.m_j(\sigma') \downarrow$. By (11b) we thus know that

$$\begin{aligned} F_{\mathbf{St}}(e, e)(\sigma, \phi).l.m_j(\sigma') &= (v, e_1(\sigma'')) \\ &\text{where } (v, \sigma'') = \sigma.l.m_j(e_1(\sigma')) \end{aligned}$$

for some $v \in \mathbf{Val}$ and $\sigma'' \in \mathbf{St}$. By (10), assumption $(\sigma', \phi') \in Y'_\Sigma$, shows $e(\sigma', \phi') =$

$(e_1(\sigma'), e_2(\phi')) \in Y_{\Sigma'}$. Together with the assumption $(\sigma, \phi) \in \Phi(Y, X)_{\Sigma}$ and (11c) this entails

$$F_{\text{RSF}}(e, e)(\phi).l.m_j(\sigma', \phi', \Sigma') = (\Sigma'', e_2(\phi''))$$

where $(\Sigma'', \phi'') = \phi.l.m_j(e_1(\sigma'), e_2(\phi'), \Sigma')$

for $\phi'' \in \text{RSF}$ and $\Sigma'' \succ \Sigma'$ such that

$$\begin{aligned} \text{(M1')} \quad & (\pi_{\text{Val}}(e_1(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket T[l/y_j] \rrbracket \\ \text{(M2')} \quad & (\sigma'', \phi'') \in X_{\Sigma''} \\ \text{(M3)} \quad & v \in \llbracket B_j[l/y_j] \rrbracket_{\Sigma''} \end{aligned}$$

Since by assumption $e_1 \sqsubseteq id_{\text{St}}$ we know $e_1(\sigma'') \sqsubseteq \sigma''$, and in particular $\pi_{\text{Val}}(e_1(\sigma'')) = \pi_{\text{Val}}(\sigma'')$. Similarly for σ' , $\pi_{\text{Val}}(e_1(\sigma')) = \pi_{\text{Val}}(\sigma')$ since $\sigma' \sqsupseteq e_1(\sigma')$. Hence, (M1') entails $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(e_1(\sigma''))) \in \llbracket T[l/y_j] \rrbracket$, i.e., (M1) holds. Finally, assumption (10) and (M2') give $(e_1(\sigma''), e_2(\phi'')) \in X'_{\Sigma''}$, which shows (M2), and we have proved (†). \square

Note that our proof of property (†) relies on the fact that the predicates denoting transition specifications are upward-closed in the pre-execution store and downward-closed in the post-execution store. This holds in Abadi-Leino logic as transition specifications are only defined on the flat part of the store. If they referred to the method part, (†) could not necessarily be shown, unless one finds an appropriate way to restrict the reference to methods in transitions specifications. See (Reus and Streicher, 2004) for more discussion and some suggestions on how to lift this restriction.

5. Soundness

In this section we present a new soundness proof of Abadi and Leino's logic using denotational semantics. Before we can embark on this endeavour we need to define the semantics of judgements $\Gamma \vdash a : A :: T$, which provides a notion of *validity* of those judgements. We write $\Gamma \vDash a : A :: T$ for the semantics of judgement $\Gamma \vdash a : A :: T$. *Soundness* means that every judgement that is derivable is indeed valid.

The definition of validity has to be assembled in a compositional way from the semantics of the constituents of the judgement, which have been discussed in the previous sections. The definition must also take into consideration that the initial store in which the program a is executed may contain methods that are called by a . Store specifications have been introduced exactly for this purpose. The context Γ specifies objects that are referred to by variables of the environment, but which actually lie in the store. This means context specification and store specification are intertwined. Due to Definition 4.4, context specifications can be interpreted with respect to store specifications Σ , which resolves this entanglement and we obtain the following definition of validity:

Definition 5.1 (Validity). $\Gamma \vDash a : A :: T$ if and only if for all store specifications $\Sigma \in \text{StSpec}$, for all $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$ and all $\sigma \in \llbracket \Sigma \rrbracket$, if $\llbracket a \rrbracket \rho \sigma = (v, \sigma')$ then $(v, \sigma') \in \llbracket [\Gamma] \vdash A \rrbracket \rho$ and $(\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho$.

Thus $\Gamma \vDash a : A :: T$ states the following: Suppose program $\llbracket a \rrbracket$ returns (v, σ) when run in a

store σ that satisfies some store specification Σ (and therefore does not contain any code that violates the restrictions needed for the logic, see also the discussion in Section 4) and in an environment ρ that satisfies Γ with respect to σ (expressed via reference to Σ). Then (v, σ) satisfies specification $\llbracket[\Gamma] \vdash A\rrbracket\rho$ and the state transformation provoked satisfies $\llbracket[\Gamma] \vdash T\rrbracket\rho$.

The rest of this section is dedicated to the proof of the soundness theorem (Theorem 5.5) which relies on a number of properties which are derived in the following.

Recall from the previous section that the semantics of store specifications is defined in terms of the semantics $\|A\|_\Sigma$ for result specifications A without any reference to object specification $\llbracket A \rrbracket$ at all. The following key lemma establishes the relation between the store specifications of Section 4 and object specifications $\llbracket A \rrbracket$ as defined in Section 3.3:

Lemma 5.2. For all object specifications A , store specifications Σ , stores σ , and locations l , if $\sigma \in \llbracket \Sigma \rrbracket$ and $l \in \text{dom}(\Sigma)$ such that $\vdash \Sigma.l <: A$ then $(l, \sigma) \in \llbracket A \rrbracket$.

Proof. By induction on the structure of A . Because A is an object specification it is necessarily of the form

$$A \equiv [f_i : A_i^{i=1 \dots n}, m_j : \varsigma(y_j) B_j :: T_j^{j=1 \dots m}]$$

We have to show that $(l, \sigma) \in \llbracket A \rrbracket$, i.e., that

- $(\sigma.l.f_i, \sigma) \in \llbracket A_i \rrbracket$ for all $1 \leq i \leq n$; and
- if $\sigma.l.m_j(\sigma) = (v, \sigma')$ then $(v, \sigma') \in \llbracket y_j \vdash B_j \rrbracket(y_j \mapsto l)$ and $(\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in \llbracket y_j \vdash T_j \rrbracket(y_j \mapsto l)$ for all $1 \leq j \leq m$.

From the subtyping relation and $\Sigma.l <: A$ we find

$$\Sigma.l \equiv [f_i : A_i^{i=1 \dots n+p}, m_j : \varsigma(y_j) B'_j :: T'_j^{j=1 \dots m+p}]$$

where $y_j \vdash B'_j <: B_j$ and $y_j \vdash_{\text{fo}} T'_j \rightarrow T_j$.

For the first part, by Definition 4.6 (F) and $\sigma \in \llbracket \Sigma \rrbracket$ we have $\sigma.l.f_i \in \|A_i\|_\Sigma$. If A_i is *Bool* then $\|A_i\|_\Sigma = \text{BVal}$, hence, $(\sigma.l.f_i, \sigma) \in \llbracket \text{Bool} \rrbracket = \llbracket A_i \rrbracket$. Otherwise A_i is an object specification and the definition of $\|A_i\|_\Sigma$ implies $\vdash \Sigma.(\sigma.l.f_i) <: A_i$, again by Definition 4.6 (F). Hence by induction hypothesis we obtain $(\sigma.l.f_i, \sigma) \in \llbracket A_i \rrbracket$ as required.

For the second part, suppose that $\sigma.l.m_j(\sigma) = (v, \sigma')$. From Definition 4.6 (M2) and (M3), and the assumption $\sigma \in \llbracket \Sigma \rrbracket$, we find $v \in \|B'_j[l/y_j]\|_{\Sigma''}$ and $\sigma'' \in \llbracket \Sigma'' \rrbracket$ for some $\Sigma'' \succ \Sigma$. In the case where B_j is *Bool* we therefore have $v \in \text{BVal}$ and obtain

$$(v, \sigma'') \in \llbracket \text{Bool} \rrbracket = \llbracket y_j \vdash \text{Bool} \rrbracket(y_j \mapsto l)$$

Next, if B_j is an object specification then by definition of $\|B'_j[l/y_j]\|_{\Sigma''}$

$$\vdash \Sigma''.v <: B'_j[l/y_j]$$

By induction hypothesis (applied to $B'_j[l/y_j]$, Σ'' , σ'' and v), $(v, \sigma'') \in \llbracket B'_j[l/y_j] \rrbracket$. Thus,

$$\begin{aligned} (v, \sigma'') \in \llbracket B'_j[l/y_j] \rrbracket &= \llbracket y_j \vdash B'_j \rrbracket(y_j \mapsto l) && \text{by substitution lemma (Lemma 4.2)} \\ &\subseteq \llbracket y_j \vdash B_j \rrbracket(y_j \mapsto l) && \text{by subtype soundness (Lemma 3.5)} \end{aligned}$$

as required.

Finally, by Definition 4.6 (M1) we obtain

$$\begin{aligned} (\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma'')) &\in \llbracket T'_j[l/y_j] \rrbracket = \llbracket y_j \vdash T'_j \rrbracket(y_j \mapsto l) && \text{by substitution (Lemma 4.2)} \\ &\subseteq \llbracket y_j \vdash T_j \rrbracket(y_j \mapsto l) && \text{by soundness of } \vdash_{\text{fo}} \end{aligned}$$

This concludes the proof. \square

Before proving the main technical result in Lemma 5.4 we state the following fact about the transition relation that appears in the let rule:

Lemma 5.3. Suppose that for $\sigma, \sigma', \sigma'' \in \text{St}$ and $v, v' \in \text{Val}$, we have $(\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in \llbracket \bar{x} \vdash T' \rrbracket \rho$ and $(\pi_{\text{Val}}(\sigma'), v', \pi_{\text{Val}}(\sigma'')) \in \llbracket \bar{x}, x \vdash T'' \rrbracket \rho[x := v]$. Then, if $\bar{x} \vdash T$ and

$$\begin{aligned} &\vdash_{\text{fo}} T'[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{post}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{post}}(\cdot), x/\text{result}] \\ &\wedge T''[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{pre}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{pre}}(\cdot)] \rightarrow T \end{aligned} \quad (12)$$

then $(\pi_{\text{Val}}(\sigma), v', \pi_{\text{Val}}(\sigma'')) \in \llbracket \bar{x} \vdash T \rrbracket \rho$.

Proof. Consider an extended signature of transition relations, with additional function and predicate symbols $\text{sel}_{\text{int}}(\cdot, \cdot)$ and $\text{alloc}_{\text{int}}(\cdot)$, respectively. We extend the interpretation of transition relations (and expressions) in the natural way to operate on three stores,

$$\llbracket x_1, \dots, x_k \vdash T \rrbracket \rho : \mathcal{P}(\text{St}_{\text{Val}} \times \text{Val} \times \text{St}_{\text{Val}} \times \text{St}_{\text{Val}})$$

where the second store argument is used to interpret $\text{sel}_{\text{int}}(\cdot, \cdot)$ and $\text{alloc}_{\text{int}}(\cdot)$:

$$(\sigma, v, \hat{\sigma}, \sigma') \in \llbracket \bar{x} \vdash \text{alloc}_{\text{int}}(e) \rrbracket \rho \iff \llbracket \bar{x} \vdash e \rrbracket \rho \sigma v \hat{\sigma} \sigma' \downarrow \wedge \llbracket \bar{x} \vdash e \rrbracket \rho \sigma v \hat{\sigma} \sigma' \in \text{dom}(\hat{\sigma})$$

and

$$\llbracket \bar{x} \vdash \text{sel}_{\text{int}}(e_0, e_1) \rrbracket \rho \sigma v \hat{\sigma} \sigma' = \begin{cases} \hat{\sigma}.l.f & \text{if } \llbracket \bar{x} \vdash e_0 \rrbracket \rho \sigma v \hat{\sigma} \sigma' = l \in \text{Loc} \\ & \text{and } \llbracket \bar{x} \vdash e_1 \rrbracket \rho \sigma v \hat{\sigma} \sigma' = f \in \mathcal{F} \\ & \text{and } l \in \text{dom}(\hat{\sigma}) \text{ and } f \in \text{dom}(\hat{\sigma}.l) \\ \text{undefined} & \text{otherwise} \end{cases}$$

By assumption and using the fact that neither T' nor T'' contains the new predicates, we also have

$$\begin{aligned} (\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma'), \pi_{\text{Val}}(\sigma')) &\in \llbracket \bar{x}, x \vdash T' \rrbracket \rho[x := v] \quad \text{and} \\ (\pi_{\text{Val}}(\sigma'), v', \pi_{\text{Val}}(\sigma'), \pi_{\text{Val}}(\sigma'')) &\in \llbracket \bar{x}, x \vdash T'' \rrbracket \rho[x := v] \end{aligned}$$

Thus,

$$\begin{aligned} &(\pi_{\text{Val}}(\sigma), v', \pi_{\text{Val}}(\sigma'), \pi_{\text{Val}}(\sigma'')) \in \\ &\llbracket \bar{x}, x \vdash T'[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{post}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{post}}(\cdot), x/\text{result}] \rrbracket \rho[x := v] \end{aligned}$$

since there are no occurrences of $\text{sel}_{\text{post}}(\cdot, \cdot)$, $\text{alloc}_{\text{post}}(\cdot)$ and result , and

$$\begin{aligned} &(\pi_{\text{Val}}(\sigma), v', \pi_{\text{Val}}(\sigma'), \pi_{\text{Val}}(\sigma'')) \in \\ &\llbracket \bar{x}, x \vdash T''[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{pre}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{pre}}(\cdot)] \rrbracket \rho[x := v] \end{aligned}$$

since there are no occurrences of $\text{sel}_{\text{pre}}(\cdot, \cdot)$ and $\text{alloc}_{\text{pre}}(\cdot)$. From soundness of first-order

provability and assumption (12) we obtain

$$(\pi_{\text{Val}}(\sigma), v', \pi_{\text{Val}}(\sigma'), \pi_{\text{Val}}(\sigma'')) \in \llbracket \bar{x}, x \vdash T \rrbracket \rho[x := v]$$

and the result follows since T does not depend on x and the new predicates, by $\bar{x} \vdash T$. \square

5.1. The Invariance Lemma

In this subsection we state and prove the main lemma of the soundness proof. Intuitively, it shows that store specifications Σ are “invariant” under proved programs,

$$\sigma \in \llbracket \Sigma \rrbracket \wedge \llbracket a \rrbracket \rho \sigma = (v, \sigma') \implies \exists \Sigma' \succcurlyeq \Sigma. \sigma' \in \llbracket \Sigma' \rrbracket \quad (13)$$

Note that the program a will in general allocate further objects, so the resulting store only satisfies an extension of the original store specification. The precise conditions of when (13) holds are given in the statement of the following lemma, and take the choice functions $\phi \in \text{RSF}$ introduced in Section 4 into account. We write SF for the domain of “individual” choice functions,

$$\text{SF} = [\text{St} \times \text{RSF} \times \text{StSpec} \rightarrow \text{StSpec} \times \text{RSF}]$$

for which $\text{RSF} = \text{Rec}_{\text{Loc}}(\text{Rec}_{\mathcal{M}}(\text{SF}))$.

Lemma 5.4. Suppose

- (H1) $\Gamma \vdash a : A :: T$
- (H2) $\Sigma \in \text{StSpec}$ is a store specification
- (H3) $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$

Then there exists $\phi \in \text{SF}$ such that, for all $\Sigma' \succcurlyeq \Sigma$ and for all $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$, if $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'') \downarrow$ then the following holds:

- (S1) $\exists \Sigma'' \succcurlyeq \Sigma' \exists \phi'' \in \text{RSF}. \phi(\sigma', \phi', \Sigma') = (\Sigma'', \phi'')$
- (S2) $(\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$
- (S3) $v \in \llbracket A[\rho/\Gamma] \rrbracket_{\Sigma''}$
- (S4) $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho$

Proof. The proof is by induction on the derivation of $\Gamma \vdash a : A :: T$.

- Lemma 4.5 is applied in the cases `LET` and `OBJECT CONSTRUCTION`, where an extended specification context is used in the induction hypothesis.
- Invariance of subspecifications in field specifications is needed in the case for `FIELD UPDATE`.
- In the cases where the store changes, i.e., `OBJECT CONSTRUCTION` and `FIELD UPDATE`, we must show explicitly that the resulting store satisfies the store specification, according to Definition 4.6. In this case one makes use of the fact that methods in the semantics of store specifications are specified using arbitrary store arguments that recursively fulfil the same store specification. This provides a sufficiently strong hypothesis to deal with the changed store.

We consider cases, depending on the last rule applied in the derivation of the judgement $\Gamma \vdash a : A :: T$.

— SUBSUMPTION

Suppose that $\Gamma \vdash a : A :: T$ has been obtained by an application of the subsumption rule, and that

(H2) Σ is a store specification

(H3) $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$

We have to show that there is $\phi \in \mathbf{SF}$ such that whenever $\Sigma' \succcurlyeq \Sigma$, $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and $\llbracket a \rrbracket \rho \sigma' = (v, \sigma')$ then (S1)–(S4) hold.

Recall the subsumption rule,

$$\frac{\Gamma \vdash A' <: A \quad \Gamma \vdash a : A' :: T' \quad [\Gamma] \vdash A \quad [\Gamma] \vdash T \quad \vdash_{\text{fo}} T' \rightarrow T}{\Gamma \vdash a : A :: T}$$

so we must have $\Gamma \vdash a : A' :: T'$ for some specification A' and transition relation T' with $\vdash_{\text{fo}} T' \rightarrow T$ and $[\Gamma] \vdash A' <: A$. By induction hypothesis there exists $\phi \in \mathbf{SF}$ such that for all $\Sigma' \succcurlyeq \Sigma$, $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ with $\llbracket a \rrbracket \rho \sigma' = (v, \sigma')$,

(S1) there exists $\Sigma'' \succcurlyeq \Sigma'$ and $\phi'' \in \mathbf{RSF}$ such that $\phi(\sigma', \phi', \Sigma') = (\Sigma'', \phi'')$

(S2) $(\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$

(S3') $v \in \llbracket A'[\rho/\Gamma] \rrbracket_{\Sigma'}$

(S4') $(\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in \llbracket [\Gamma] \vdash T' \rrbracket \rho$

Because $\vdash_{\text{fo}} T' \rightarrow T$ we know $\llbracket [\Gamma] \vdash T' \rrbracket \rho \subseteq \llbracket [\Gamma] \vdash T \rrbracket \rho$, and therefore (S4') implies

$$(\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho \quad (\text{S4})$$

It remains to show

$$v \in \llbracket A[\rho/\Gamma] \rrbracket_{\Sigma'} \quad (\text{S3})$$

Note that by the subtyping rules, $A \equiv \text{Bool}$ if and only if $A' \equiv \text{Bool}$. In this case (S3) follows directly from (S3'). In the case where A' is an object specification, assumption $[\Gamma] \vdash A' <: A$ and Lemma 4.2 entail $\vdash A'[\rho/\Gamma] <: A[\rho/\Gamma]$. Transitivity of $<:$ and (S3') then prove (S3), by the definition of $\llbracket A'[\rho/\Gamma] \rrbracket_{\Sigma'}$.

— VAR

Suppose $\Gamma \vdash a : A :: T$ has been derived by an application of the VAR rule

$$\frac{\Gamma \vdash \text{ok} \quad x : A \text{ in } \Gamma}{\Gamma \vdash x : A :: T_{\text{res}}(x)}$$

for which we see that $a \equiv x$, $x : A$ in Γ , and $T \equiv T_{\text{res}}(x)$. Further, assume

(H2) $\Sigma \in \text{StSpec}$

(H3) $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$

Define the (partial continuous) map $\phi \in \mathbf{SF}$ by

$$\phi(\sigma', \phi', \Sigma') = (\Sigma', \phi')$$

Now suppose $\Sigma' \succcurlyeq \Sigma$, $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'')$. By the assumptions and the semantics of variables we obtain $(v, \sigma'') = (\rho(x), \sigma')$, i.e.,

$$v = \rho(x) \quad \wedge \quad \sigma'' = \sigma' \quad (14)$$

By definition of ϕ above we can choose Σ'' as Σ' , for then

$$(S1) \phi(\sigma', \phi', \Sigma') = (\Sigma', \phi')$$

$$(S2) (\sigma'', \phi') \in \text{fix}(\Phi)_{\Sigma'}, \text{ by } \sigma'' = \sigma' \text{ and assumption } (\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$$

$$(S3) v \in \|A[\rho/\Gamma]\|_{\Sigma'}, \text{ by } v = \rho(x), \text{ by } x:A \in \Gamma \text{ and (H3)}$$

$$(S4) (\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma] \vdash T_{\text{res}}(x) \rrbracket \rho, \text{ by the definition of } \llbracket [\Gamma] \vdash T \rrbracket \text{ in Table 8 and (14)}$$

as required.

— CONST

Similar to the previous case.

— CONDITIONAL

By a case distinction, depending on whether the value of the guard x is *true* or *false*.

— LET

Suppose (H1) $\Gamma \vdash a : A :: T$ has been derived by an application of the LET rule.

Hence, a is **let** $x = a_1$ **in** a_2 . Assume that

$$(H2) \Sigma \in \text{StSpec} \text{ is a store specification, and}$$

$$(H3) \rho \in \|\Gamma\|_{\Sigma}$$

Now recall the rule for this case,

$$\frac{\begin{array}{c} \Gamma \vdash a_1 : A_1 :: T_1 \quad \Gamma, x:A_1 \vdash a_2 : A :: T_2 \quad [\Gamma] \vdash A \quad [\Gamma] \vdash T \\ \vdash_{\text{fo}} T_1[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{post}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{post}}(\cdot), x/\text{result}] \\ \wedge T_2[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{pre}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{pre}}(\cdot)] \rightarrow T \end{array}}{\Gamma \vdash \text{let } x = a_1 \text{ in } a_2 : A :: T}$$

By the premiss of this rule we must have

$$(H1') \Gamma \vdash a_1 : A_1 :: T_1$$

$$(H1'') \Gamma, x:A_1 \vdash a_2 : A :: T_2$$

By induction hypothesis applied to (H1') there is $\phi_1 \in \text{SF}$ such that, for all $\Sigma' \succcurlyeq \Sigma$ and $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ with $\llbracket a_1 \rrbracket \rho \sigma' = (\hat{v}, \hat{\sigma})$, the conclusions of the lemma hold:

$$(S1') \text{ there exists } \hat{\Sigma} \succcurlyeq \Sigma' \text{ and } \hat{\phi} \in \text{RSF} \text{ such that } \phi_1(\sigma', \phi', \Sigma') = (\hat{\Sigma}, \hat{\phi})$$

$$(S2') (\hat{\sigma}, \hat{\phi}) \in \text{fix}(\Phi)_{\hat{\Sigma}}$$

$$(S3') \hat{v} \in \|A_1[\rho/\Gamma]\|_{\hat{\Sigma}}$$

$$(S4') (\pi_{\text{Val}}(\sigma'), \hat{v}, \pi_{\text{Val}}(\hat{\sigma})) \in \llbracket [\Gamma] \vdash T_1 \rrbracket \rho$$

In particular, by conclusion (S3') and context extension (Lemma 4.5),

$$\rho[x := \hat{v}] \in \|\Gamma, x:A_1\|_{\hat{\Sigma}}$$

Therefore, by induction hypothesis applied to (H1'') there is $\phi_{\hat{\Sigma}\hat{v}} \in \text{SF}$ such that, for all $\Sigma' \succcurlyeq \hat{\Sigma}$ and all $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ with $\llbracket a_2 \rrbracket \rho[x := \hat{v}] \sigma' = (v, \sigma'')$, the following holds.

$$(S1'') \text{ there exists } \Sigma'' \succcurlyeq \Sigma' \text{ and } \phi'' \in \text{RSF} \text{ such that } \phi_{\hat{\Sigma}\hat{v}}(\sigma', \phi', \Sigma') = (\Sigma'', \phi'')$$

$$(S2'') (\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$$

$$(S3'') v \in \|A[\rho[x := \hat{v}]/\Gamma, x:A_1]\|_{\Sigma''}$$

(S4'') $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma, x:A_1] \vdash T_2 \rrbracket \rho$

Now define $\phi \in \text{SF}$ for all σ', ϕ' and Σ' by

$$\phi(\sigma', \phi', \Sigma') = \begin{cases} \phi_{\hat{\Sigma}\hat{\sigma}}(\hat{\sigma}, \hat{\phi}, \hat{\Sigma}) & \text{if } \llbracket a_1 \rrbracket \rho \sigma' = (\hat{v}, \hat{\sigma}) \wedge \phi_1(\sigma', \phi', \Sigma') = (\hat{\Sigma}, \hat{\phi}) \\ \text{undefined} & \text{otherwise} \end{cases}$$

which is continuous as all its constituents are, and since Val and StSpec are flat.

We show that the conclusion of the lemma holds. Let $\Sigma' \succ \Sigma$, let $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and suppose $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'')$. From the definition of the semantics,

$$(v, \sigma'') = \mathbf{let} \ (\hat{v}, \hat{\sigma}) = \llbracket a_1 \rrbracket \rho \sigma' \ \mathbf{in} \ \llbracket a_2 \rrbracket \rho[x := \hat{v}] \hat{\sigma}$$

which shows

- $\llbracket a_1 \rrbracket \rho \sigma' = (\hat{v}, \hat{\sigma})$
- $\llbracket a_2 \rrbracket \rho[x := \hat{v}] \hat{\sigma} = (v, \sigma'')$

We now show that ϕ defined above does fulfill the necessary requirements:

- (S1) there is $\Sigma'' \in \text{StSpec}$ such that $\Sigma'' \succ \hat{\Sigma} \succ \Sigma'$ and $\phi(\sigma', \phi', \Sigma') = \phi_{\hat{\Sigma}\hat{\sigma}}(\hat{\sigma}, \hat{\phi}, \hat{\Sigma}) = (\Sigma'', \phi'')$, where $\phi_1(\sigma', \phi', \Sigma') = (\hat{\Sigma}, \hat{\phi})$, by (S1') and (S1'')
- (S2) $(\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$, by (S2') and (S2'')
- (C3) $v \in \llbracket A[\rho[x := \hat{v}]/\Gamma, x:A_1] \rrbracket_{\Sigma''}$, by (S3') and (S3'')
- (C4') $(\pi_{\text{Val}}(\sigma'), \hat{v}, \pi_{\text{Val}}(\hat{\sigma})) \in \llbracket [\Gamma] \vdash T_1 \rrbracket \rho$, by (S4')
- (C4'') $(\pi_{\text{Val}}(\hat{\sigma}), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma, x:A_1] \vdash T_2 \rrbracket \rho[x := \hat{v}]$, by (S4'')

Since $[\Gamma] \vdash A$, i.e., x is not free in A , we have

$$A[\rho[x := v]/(\Gamma, x:A_1)] \equiv A[\rho/\Gamma] \quad (15)$$

Moreover, (C4'), (C4''), Lemma 5.3 and

$$\begin{aligned} & \vdash_{\text{fo}} T_1[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{post}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{post}}(\cdot), x/\text{result}] \\ & \wedge T_2[\text{sel}_{\text{int}}(\cdot, \cdot)/\text{sel}_{\text{pre}}(\cdot, \cdot), \text{alloc}_{\text{int}}(\cdot)/\text{alloc}_{\text{pre}}(\cdot)] \rightarrow T \end{aligned}$$

proves

$$(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho \quad (16)$$

We therefore obtain

- (S3) $v \in \llbracket A[\rho/\Gamma] \rrbracket_{\Sigma'}$, by (C3) and (15) as Σ'' extends Σ'
- (S4) $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho$, by (16)

as required.

— OBJECT CONSTRUCTION

Suppose (H1): $\Gamma \vdash a : A :: T$ has been derived by an application of rule OBJECT CONSTRUCTION. Necessarily $a \equiv [f_i = x_i^{i=1\dots n}, m_j = \zeta(y_j)b_j^{j=1\dots m}]$. Suppose that

- (H2) $\Sigma \in \text{StSpec}$
- (H3) $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$

We recall the object introduction rule,

$$\frac{A \equiv [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}] \quad \Gamma \vdash x_i: A_i :: T_{\text{res}}(x_i)^{i=1\dots n} \quad \Gamma, y_j: A \vdash b_j: B_j::T_j^{j=1\dots m}}{\Gamma \vdash [f_i = x_i^{i=1\dots n}, m_j = \varsigma(y_j)b_j^{j=1\dots m}]: A::T_{\text{obj}}(f_1 = x_1 \dots f_n = x_n)}$$

from which we see that A is $[f_i: A_i, m_j: B_j::T_j]$, that T is $T_{\text{obj}}(f_1 = x_1 \dots f_n = x_n)$ and that

$$(H1') \quad \Gamma \vdash x_i : A_i :: T_{\text{res}}(x_i) \text{ for } 1 \leq i \leq n$$

$$(H1'') \quad \Gamma, y_j: A \vdash b_j : B_j :: T_j \text{ for } 1 \leq j \leq m$$

We have to show that there is $\phi \in \mathbf{SF}$ such that, for all $\Sigma' \succcurlyeq \Sigma$ and all $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ with $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'')$, conditions (S1)–(S4) hold.

From (H3) and context extension (Lemma 4.5) we know that for all $\hat{\Sigma} \succcurlyeq \Sigma$ and $l_0 \in \llbracket A[\rho/\Gamma] \rrbracket_{\hat{\Sigma}}$,

$$\rho[y_j := l_0] \in \llbracket \Gamma, y_j: A \rrbracket_{\hat{\Sigma}}$$

Hence by induction hypothesis on (H1''), for all $1 \leq j \leq m$ there is $\phi_{\hat{\Sigma} l_0}^j \in \mathbf{SF}$ such that, for all $\Sigma_1 \succcurlyeq \hat{\Sigma}$ and all $(\sigma_1, \phi_1) \in \text{fix}(\Phi)_{\Sigma_1}$ with $\llbracket b_j \rrbracket \rho[y_j := l_0] \sigma_1 = (v_2, \sigma_2) \downarrow$, we obtain the conclusions (S1)–(S4) of the lemma, i.e.,

$$(S1') \quad \text{there exists } \Sigma_2 \succcurlyeq \Sigma_1 \succcurlyeq \hat{\Sigma} \text{ and } \phi_2 \in \mathbf{RSF} \text{ such that } \phi_{\Sigma_2 l_0}^j(\sigma_1, \phi_1, \Sigma_1) = (\Sigma_2, \phi_2)$$

$$(S2') \quad (\sigma_2, \phi_2) \in \text{fix}(\Phi)_{\Sigma_2}$$

$$(S3') \quad v_2 \in \llbracket B_j[\rho[y_j := l_0]/\Gamma, y_j: A] \rrbracket_{\Sigma_2}$$

$$(S4') \quad (\pi_{\text{Val}}(\sigma_1), v_2, \pi_{\text{Val}}(\sigma_2)) \in \llbracket [\Gamma, y_j: A] \vdash T_j \rrbracket \rho[y_j := l_0]$$

Now we can define $\phi \in \mathbf{SF}$ as follows

$$\phi(\sigma', \phi', \Sigma') = \begin{cases} ((\Sigma', l_0: A[\rho/\Gamma]), \phi' + \{l_0 = \{m_j = \phi_{(\Sigma', l_0: A[\rho/\Gamma]) l_0}^j\}\}) & \text{if } \Sigma' \succcurlyeq \Sigma \text{ and } \llbracket a \rrbracket \rho \sigma' = (l_0, \sigma'') \\ \text{undefined} & \text{otherwise} \end{cases} \quad (17)$$

which is continuous as all constituents are and $StSpec$ is a flat cpo. We show that (S1)–(S4) hold. Let $\Sigma' \succcurlyeq \Sigma$, let $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and suppose $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'')$. By definition of the semantics, and the fact that (H1') entails $\rho(x_i) \downarrow$ for $1 \leq i \leq n$, for $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'') \in \text{Loc} \times \text{St}$ we obtain $v = l_0$ where $l_0 \notin \text{dom}(\sigma')$ (and so $l_0 \notin \text{dom}(\Sigma')$) and

$$\sigma'' = \sigma' + \{l_0 = \{f_i = \rho(x_i), m_j = \lambda \sigma. \llbracket b_j \rrbracket \rho[y_j := l_0] \sigma\}\} \quad (18)$$

We obtain that there exists $\phi'' \in \mathbf{RSF}$ such that

$$(S1) \quad \phi(\sigma', \phi', \Sigma') = ((\Sigma', l_0: A[\rho/\Gamma]), \phi''), \text{ by construction of } \phi \text{ in (17)}$$

$$(S3) \quad v = l_0 \in \llbracket A[\rho/\Gamma] \rrbracket_{(\Sigma', l_0: A[\rho/\Gamma])}, \text{ by definition of } \llbracket \cdot \rrbracket$$

$$(S4) \quad (\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma \vdash T_{\text{obj}}(f_1 = x_1 \dots f_n = x_n)] \rrbracket \rho, \text{ which is easily checked from the definition of } T_{\text{obj}}(\dots), \text{ the semantics in Table 8 and equation (18).}$$

All that remains to be shown is (S2): $(\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$, where Σ'' is $\Sigma', l_0: A[\rho/\Gamma]$.

By the construction of ϕ in (17),

$$\phi'' = \phi' + \{\{l_0 = \{\mathbf{m}_j = \phi_{(\Sigma', l_0: A[\rho/\Gamma]) l_0}^j\}\}\}$$

We show (S2) according to Definition 4.6:

Firstly, by assumption the domains of ϕ' and Σ' agree so (DOM1) holds. By construction of ϕ , also $\text{dom}(\phi'' \cdot l_0) = \{\mathbf{m}_1, \dots, \mathbf{m}_m\}$ from which (DOM2) follows. For the remaining conditions, suppose $l \in \text{dom}(\Sigma'')$. We distinguish two cases:

– $l \neq l_0$: Then

$$\Sigma'' \cdot l = \Sigma' \cdot l = [\mathbf{g}_i: A_i^{i=1 \dots p}, \mathbf{n}_j: \varsigma(y_j) B'_j :: T_j^{1 \dots q}]$$

(F) For all $1 \leq i \leq p$, $\sigma'' \cdot l \cdot \mathbf{g}_i = \sigma' \cdot l \cdot \mathbf{g}_i$, and so from $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$

$$\sigma'' \cdot l \cdot \mathbf{g}_i \in \|A_i\|_{\Sigma'} \subseteq \|A_i\|_{\Sigma''}$$

(M) Let $1 \leq j \leq q$, let $\Sigma_1 \succcurlyeq \Sigma''$, let $(\sigma_1, \phi_1) \in \text{fix}(\Phi)_{\Sigma_1}$ and suppose $\sigma'' \cdot l \cdot \mathbf{n}_j(\sigma_1) = (v_2, \sigma_2)$. Since $\sigma'' \cdot l \cdot \mathbf{n}_j = \sigma' \cdot l \cdot \mathbf{n}_j$ and $\Sigma_1 \succcurlyeq \Sigma'$, the assumption $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and the construction of ϕ'' entails that there exists $\Sigma_2 \succcurlyeq \Sigma_1$ and $\phi_2 \in \text{RSF}$ such that $\phi'' \cdot l \cdot \mathbf{n}_j(\sigma_1, \phi_1, \Sigma_1) = \phi' \cdot l \cdot \mathbf{n}_j(\sigma_1, \phi_1, \Sigma_1) = (\Sigma_2, \phi_2)$ and

$$(M1) (\pi_{\text{Val}}(\sigma_1), v_2, \pi_{\text{Val}}(\sigma_2)) \in \llbracket T_j[l/y_j] \rrbracket$$

$$(M2) (\sigma_2, \phi_2) \in \text{fix}(\Phi)_{\Sigma_2}$$

$$(M3) v_2 \in \|B'_j[l/y_j]\|_{\Sigma_2}$$

– $l = l_0$:

(F) By assumption (H1') and $\rho \in \|\Gamma\|_{\Sigma}$ we know that there is $\vdash A_i' <: A_i$ for all $1 \leq i \leq n$ such that $x_i: A_i'$ in Γ . Hence,

$$\sigma'' \cdot l_0 \cdot \mathbf{f}_i = \rho(x_i) \in \|A_i'\|_{\Sigma} \subseteq \|A_i\|_{\Sigma} \subseteq \|A_i\|_{\Sigma''}$$

(M) Let $1 \leq j \leq m$. Suppose $\Sigma_1 \succcurlyeq \Sigma''$, let $(\sigma_1, \phi_1) \in \text{fix}(\Phi)_{\Sigma_1}$ and suppose $\sigma'' \cdot l_0 \cdot \mathbf{m}_j(\sigma_1) = (v_2, \sigma_2)$. Since $\sigma'' \cdot l_0 \cdot \mathbf{m}_j = \llbracket b_j \rrbracket \rho[y_j := l_0] \sigma_1$ and $\Sigma_1 \succcurlyeq \Sigma''$, and $(\sigma_1, \phi_1) \in \text{fix}(\Phi)_{\Sigma_1}$ by setting $\hat{\Sigma} := \Sigma''$ from (S1') we get $\phi_{\Sigma'' \cdot l_0}^j(\sigma_1, \phi_1, \Sigma_1) = (\Sigma_2, \phi_2)$ and so we obtain the required Σ_2 and ϕ_2 such that

$$\phi'' \cdot l_0 \cdot \mathbf{m}_j(\sigma_1, \phi_1, \Sigma_1) = (\Sigma_2, \phi_2)$$

by definition of ϕ'' . Thus, we can prove the remaining goals:

$$(M1) (\pi_{\text{Val}}(\sigma_1), v_2, \pi_{\text{Val}}(\sigma_2)) \in \llbracket [\Gamma, y_j: A] \vdash T_j \rrbracket \rho[y_j := l_0] = \llbracket T_j[\rho/\Gamma][l_0/y_j] \rrbracket, \text{ by (S4')}$$

$$(M2) (\sigma_2, \phi_2) \in \text{fix}(\Phi)_{\Sigma_2}, \text{ by (S2')}$$

$$(M3) v_2 \in \|B_j[\rho[y_j := l_0]/\Gamma, y_j: A]\|_{\Sigma_2} = \|B_j[\rho/\Gamma][l_0/y_j]\|_{\Sigma_2}, \text{ by (S3')}$$

where the equations in (M1) and (M2) are by applications of the substitution lemma, Lemma 4.2.

Thus we have shown $(\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$, i.e., (S2) holds.

— METHOD INVOCATION

Suppose $\Gamma \vdash a : A :: T$ is derived by an application of the METHOD INVOCATION rule:

$$\frac{\Gamma \vdash x : [\mathbf{m} : \zeta(y)A' :: T'] :: T_{\text{res}}(x)}{\Gamma \vdash x.\mathbf{m} : A'[x/y] :: T'[x/y]}$$

Necessarily a is of the form $x.\mathbf{m}$ and there are A' and T' such that $A \equiv A'[x/y]$ and $T \equiv T'[x/y]$. So suppose

(H1) $\Gamma \vdash a : A'[x/y] :: T'[x/y]$

(H2) Σ is a store specification

(H3) $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$

Define $\phi \in \mathbf{SF}$ using “self-application” of the argument,

$$\phi(\sigma', \phi', \Sigma') = \phi'.\rho(x).\mathbf{m}(\sigma', \phi', \Sigma') \quad (19)$$

Now let $\Sigma' \succcurlyeq \Sigma$, $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and suppose $\llbracket a \rrbracket \rho \sigma' = \sigma'.\rho(x).\mathbf{m}(\sigma') = (v, \sigma'')$ terminates. We show that (S1)–(S4) hold.

By the hypothesis of the method invocation rule, we can assume

$$\Gamma \vdash x : [\mathbf{m} : \zeta(y)A' :: T'] :: T_{\text{res}}(x) \quad (\text{H1}')$$

Since this implies $x : B \in \Gamma$ for some $[\Gamma] \vdash B <: [\mathbf{m} : \zeta(y)A' :: T']$, by assumption (H3) this entails

$$\vdash \Sigma'.(\rho(x)) <: [\mathbf{m} : \zeta(y)A' :: T'] [\rho/\Gamma]$$

i.e., there are A_i, A'', B_j and T_j, T'' such that

$$\vdash \Sigma'.\rho(x) \equiv [\mathbf{f}_i : A_i, \mathbf{m}_j : \zeta(y_j)B_j :: T_j, \mathbf{m} : \zeta(y)A'' :: T'']$$

where

$$y \vdash A'' <: A'[\rho/\Gamma] \quad \wedge \quad \vdash_{\text{fo}} T'' \rightarrow T'[\rho/\Gamma] \quad (20)$$

Now assumption $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ with equation (19) implies that there are Σ'', ϕ'' such that

(S1) $\phi(\sigma', \phi', \Sigma') = \phi'.(\rho(x)).\mathbf{m}(\sigma', \phi', \Sigma') = (\Sigma'', \phi'')$

(S2) $(\sigma'', \phi'') \in \text{fix}(\Phi)_{\Sigma''}$

(S3') $v \in \llbracket A''[\rho(x)/y] \rrbracket_{\Sigma''}$

(S4') $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket T''[\rho(x)/y] \rrbracket$

By transitivity of $<:$, equation (20), Lemma 4.2 and (S3')

$$v \in \llbracket A'[\rho/\Gamma][\rho(x)/y] \rrbracket_{\Sigma''}$$

Since $A'[\rho/\Gamma, \rho(x)/y] \equiv A'[x/y][\rho/\Gamma]$ we also have

(S3) $v \in \llbracket A'[x/y][\rho/\Gamma] \rrbracket_{\Sigma''} = \llbracket A[\rho/\Gamma] \rrbracket_{\Sigma''}$

Similarly, by (20) and (S4'),

$$\begin{aligned} (\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) &\in \llbracket T''[\rho(x)/y] \rrbracket \subseteq \llbracket T'[\rho/\Gamma][\rho(x)/y] \rrbracket \\ &= \llbracket [\Gamma] \vdash T[x/y] \rrbracket \rho \end{aligned} \quad (\text{S4})$$

which was to show.

— FIELD SELECTION

Similar. ϕ can be chosen as $\phi(\sigma', \phi', \Sigma') = (\phi', \Sigma')$.

— FIELD UPDATE

Suppose

(H1) $\Gamma \vdash a:A::T$ has been derived by an application FIELD UPDATE,

(H2) Σ is a store specification

(H3) $\rho \in \|\Gamma\|_\Sigma$

Let $\Sigma' \succ \Sigma$, $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and suppose $\llbracket a \rrbracket \rho \sigma' = (v, \sigma'')$ terminates. Recall the rule for field update,

$$\frac{A \equiv [\mathbf{f}_i:A_i^{i=1\dots n}, \mathbf{m}_j:\zeta(y_j)B_j::T_j^{j=1\dots m}] \quad \Gamma \vdash x:A::T_{\text{res}}(x) \quad \Gamma \vdash y:A_k::T_{\text{res}}(y)}{\Gamma \vdash x.\mathbf{f}_k := y:A::T_{\text{upd}}(x, \mathbf{f}_k, y)} \quad (1 \leq k \leq n)$$

In particular, a is of the form $x.\mathbf{f}_k := y$ and T is $T_{\text{upd}}(x, \mathbf{f}_k, y)$. From the semantics of $\llbracket a \rrbracket \rho \sigma'$, this means $v = \rho(x) \in \text{Loc}$ and

$$\sigma'' = \sigma'[v := \sigma'.v[\mathbf{f}_k := \rho(y)]] \quad (21)$$

Let us define the required $\phi \in \mathbf{SF}$ by $\phi(\sigma', \phi', \Sigma') = (\Sigma', \phi')$ which reflects the fact that no new objects are created. We have to show that (S1)–(S4) hold.

By (H3), $\rho(x) \in \|A[\rho/\Gamma]\|_\Sigma \subseteq \|A[\rho/\Gamma]\|_{\Sigma'}$. Then by construction of ϕ and (21),

(S1) $\phi(\sigma', \phi', \Sigma') = (\Sigma', \phi')$

(S3) $v = \rho(x) \in \|A[\rho/\Gamma]\|_{\Sigma'}$

(S4) $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho$, from the semantics given in Table 8

It remains to show (S2): $(\sigma'', \phi') \in \text{fix}(\Phi)_{\Sigma'}$.

By assumption $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and $\text{dom}(\sigma'') = \text{dom}(\sigma')$, conditions (DOM1) and (DOM2) of Definition 4.6 are satisfied. As for (F) and (M), let $l \in \text{dom}(\Sigma')$ and $\Sigma'.l \equiv [\mathbf{g}_i:A_i^{i=1\dots p}, \mathbf{n}_j:\zeta(y_j)B_j'::T_j^{j=1\dots q}]$.

(F) We distinguish two cases:

- Case $l = \rho(x)$ and $\mathbf{g}_i = \mathbf{f}_k$. Then, by (21), $\sigma''.l.\mathbf{g}_i = \rho(y)$. By (H3), $\rho(x) \in \|A[\rho/\Gamma]\|_\Sigma \subseteq \|A[\rho/\Gamma]\|_{\Sigma'}$, which entails

$$\vdash \Sigma'.l <: A[\rho/\Gamma]$$

and in particular, by the definition of the subspecification relation,

$$A'_k = \Sigma'.l.\mathbf{f}_k \equiv A_k[\rho/\Gamma].$$

Note that *invariance of subspecification* in the field components is needed to conclude this. Now again by (H3),

$$\rho(y) \in \|A_k[\rho/\Gamma]\|_\Sigma \subseteq \|A_k[\rho/\Gamma]\|_{\Sigma'} = \|A'_k\|_{\Sigma'}$$

Hence, $\sigma''.l.\mathbf{g}_i \in \|A'_i\|_{\Sigma'}$ as required.

- Case $l \neq \rho(x)$ or $\mathbf{g}_i \neq \mathbf{f}_k$. Then $\sigma''.l.\mathbf{g}_i = \sigma'.l.\mathbf{g}_i$, by (21). Hence, by assumption $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$, we have $\sigma''.l.\mathbf{g}_i \in \|A'_i\|_{\Sigma'}$.

- (M) Let $\Sigma'' \succcurlyeq \Sigma'$, let $(\sigma_1, \phi_1) \in \text{fix}(\Phi)_{\Sigma''}$ and suppose $\sigma'' . l . n_j(\sigma_1) = (v_2, \sigma_2)$. Then, by assumption $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$ and the fact that $\sigma'' . l . n_j = \sigma' . l . n_j$ by (21), we obtain that $\phi' . l . n_j(\sigma_1, \phi_1, \Sigma'') = (\Sigma_2, \phi_2)$ where $\Sigma_2 \succcurlyeq \Sigma''$ and
- (M1) $(\pi_{\text{Val}}(\sigma_1), v_2, \pi_{\text{Val}}(\sigma_2)) \in \llbracket T'_j[l/y_j] \rrbracket$
 - (M2) $(\sigma_2, \phi_2) \in \text{fix}(\Phi)_{\Sigma_2}$
 - (M3) $v_2 \in \llbracket B'_j[l/y_j] \rrbracket_{\Sigma_2}$
- as required.

which concludes the proof. \square

5.2. Soundness Theorem

With Lemma 5.2 and Lemma 5.4 proved above, it is now easy to establish our main result:

Theorem 5.5 (Soundness). If $\Gamma \vdash a : A :: T$ then $\Gamma \vDash a : A :: T$.

Proof. Suppose $\Gamma \vdash a : A :: T$, and let $\Sigma \in \text{StSpec}$ be a store specification and suppose $\rho \in \text{Env}$ such that $\rho \in \llbracket \Gamma \rrbracket_{\Sigma}$. Let $\sigma \in \llbracket \Sigma \rrbracket$, so by definition there exists $\phi \in \text{RSF}$ such that $(\sigma, \phi) \in \text{fix}(\Phi)_{\Sigma}$. Next suppose

$$\llbracket a \rrbracket \rho \sigma = (v, \sigma')$$

By Lemma 5.4 there exists $\phi_a \in \text{RSF}$ such that

- (S1) $\phi_a(\sigma, \phi, \Sigma) = (\Sigma', \phi')$ where $\Sigma' \succcurlyeq \Sigma$ and
- (S2) $(\sigma', \phi') \in \text{fix}(\Phi)_{\Sigma'}$
- (S3) $v \in \llbracket A[\rho/\Gamma] \rrbracket_{\Sigma'}$
- (S4) $(\pi_{\text{Val}}(\sigma), v, \pi_{\text{Val}}(\sigma')) \in \llbracket [\Gamma] \vdash T \rrbracket \rho$

In particular, $\sigma' \in \llbracket \Sigma' \rrbracket$ follows.

Now in the case where A is *Bool* we obtain $(v, \sigma') \in \llbracket [\Gamma] \vdash A \rrbracket \rho$ from $\llbracket \text{Bool} \rrbracket_{\Sigma'} = \text{BVal}$. Otherwise A is an object specification, and we must have $\vdash \Sigma' . v <: A[\rho/\Gamma]$ by definition of $\llbracket A[\rho/\Gamma] \rrbracket_{\Sigma'}$. Hence, by Lemma 5.2,

$$(v, \sigma') \in \llbracket A[\rho/\Gamma] \rrbracket = \llbracket [\Gamma] \vdash A \rrbracket \rho$$

where the last equality is by the the substitution lemma, Lemma 4.2. \square

In particular, if $\vdash a : A :: T$ and $\llbracket a \rrbracket \sigma = (v, \sigma')$ then $(v, \sigma') \in \llbracket A \rrbracket$ and so $v \neq \text{error}$ by Lemma 3.4.

6. Recursive Specifications

In this section we investigate an extension of the logic with recursive specifications. These are necessary when a field of an object or a result of one of the object's methods are supposed to satisfy the same specification as the object itself. In particular, they are needed to specify any recursive datatype: Referring back to the example of the account manager in Table 5, if A_{Manager} should include a list of accounts, we would need a recursive specification $\mu(X)[\text{head} : A_{\text{Account}}, \text{tail} : X]$.

Below we discuss in more detail how recursive specifications can be dealt with in the logic.

6.1. Syntax and Proof Rules

To accommodate reasoning about elements of recursive types such as lists, we introduce recursive specifications $\mu(X)A$. To prevent meaningless specifications such as $\mu(X)X$ we only allow recursion through object specifications, thereby enforcing “formal contractiveness”.

$$\begin{aligned} \underline{A} ::= \top \mid \text{Bool} \mid [f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}] \mid \mu(X)\underline{A} \\ A, B ::= \underline{A} \mid X \end{aligned}$$

where X ranges over an infinite set \mathcal{SV} of specification variables. X is bound in $\mu(X)A$, and as usual we identify specifications up to the names of bound variables.

In addition to specification contexts Γ we introduce contexts Δ that contain specification variables with an upper bound, $X <: A$, where A is either another variable or \top . In the rules of the logic we replace each judgement $\Gamma \vdash a:A::T$ by $\Gamma; \Delta \vdash a:A::T$, and the definitions of well-formed specifications and well-formed specification contexts are extended, similar to the case of recursive types for the object calculus (Abadi and Cardelli, 1996),

$$\frac{\Gamma; \Delta \vdash Y \quad X \notin \Delta}{\Gamma; \Delta, X <: Y \vdash \text{ok}} \quad \frac{\Gamma; \Delta \vdash \text{ok} \quad X \notin \Delta}{\Gamma; \Delta, X <: \top \vdash \text{ok}}$$

and

$$\frac{\Gamma; \Delta, X <: A, \Delta' \vdash \text{ok}}{\Gamma; \Delta, X <: A, \Delta' \vdash X} \quad \frac{\Gamma; \Delta, X <: \top \vdash A}{\Gamma; \Delta \vdash \mu(X)A} \quad \frac{\Gamma; \Delta \vdash \text{ok}}{\Gamma; \Delta \vdash \top}$$

We will simply write Δ, X, Δ' in place of $\Delta, X <: \top, \Delta'$.

Subspecifications for recursive specifications are obtained by the “usual” recursive subtyping rule (Amadio and Cardelli, 1993), and \top is the greatest specification,

$$\begin{aligned} \text{RECSUB} \quad \frac{\Gamma; \Delta, Y <: \top, X <: Y \vdash A <: B}{\Gamma; \Delta \vdash \mu(X)A <: \mu(Y)B} \\ \text{TOP} \quad \frac{\Gamma; \Delta \vdash A}{\Gamma; \Delta \vdash A <: \top} \end{aligned}$$

As will be seen from the semantics below, in our model a recursive specification and its unfolding are not just isomorphic but equal, i.e., $\llbracket \mu(X)A \rrbracket = \llbracket A[(\mu(X)A)/X] \rrbracket$. Because of this, we do not need to introduce *fold* and *unfold* terms: We can deal with (un)folding of recursive specifications through the subsumption rule once we add the following subspecifications,

$$\begin{aligned} \text{FOLD} \quad \frac{\Gamma; \Delta \vdash \mu(X)A}{\Gamma; \Delta \vdash A[(\mu(X)A)/X] <: \mu(X)A} \\ \text{UNFOLD} \quad \frac{\Gamma; \Delta \vdash \mu(X)A}{\Gamma; \Delta \vdash \mu(X)A <: A[(\mu(X)A)/X]} \end{aligned}$$

We will prove their soundness below.

Table 13. Store specifications

$(\sigma, \phi) \in \Phi(Y, X)_\Sigma$	\iff	(DOM1) $\text{dom}(\Sigma) = \text{dom}(\phi)$; and (DOM2) $\forall l \in \text{dom}(\Sigma)$. if $\text{dom}(\Sigma.l) \equiv \mu(X)[f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$ then $\text{dom}(\phi.l) = \{m_j\}_{j=1\dots m}$; and $\forall l \in \text{dom}(\Sigma)$ where $\Sigma.l \equiv \mu(X)[f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$: (F) $\forall 1 \leq i \leq n$. $\sigma.l.f_i \in \ A_i[\Sigma.l/X]\ _\Sigma$; and (M) $\forall 1 \leq j \leq m$. $\forall \Sigma' \succcurlyeq \Sigma \forall \sigma', \sigma'' \in \text{St} \forall \phi' \in \text{RSF} \forall l' \in \text{Loc} \forall v \in \text{Val}$. if $l' \in \ \Sigma.l\ _{\Sigma'}$ \wedge $(\sigma', \phi') \in Y_{\Sigma'}$ \wedge $\sigma.l.m_j(l', \sigma') = (v, \sigma'')$ then $\exists \Sigma'' \succcurlyeq \Sigma' \exists \phi'' \in \text{RSF}$. $\phi.l.m_j(l', \sigma', \phi', \Sigma') = (\Sigma'', \phi'')$ and (M1) $(\pi_{\text{Val}}(\sigma'), v, \pi_{\text{Val}}(\sigma'')) \in [T_j[l'/y_j]]$; and (M2) $(\sigma'', \phi'') \in X_{\Sigma''}$; and (M3) $v \in \ B_j[\Sigma.l/X][l'/y_j]\ _{\Sigma''}$
--	--------	---

6.2. Existence of Store Specifications

Next, we adapt our notion of store specification to recursive specifications. This is very similar to Definition 4.6; for completeness we spell it out in detail below.

Definition 6.1. A store specification, for the purpose of the present section, is a record $\Sigma \in \text{Rec}_{\text{Loc}}(\text{Spec})$ such that for each $l \in \text{dom}(\Sigma)$, $\Sigma.l$ is a closed (recursive) object specification of the form $\mu(X)[f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$. We continue to write StSpec for the set of store specifications.

Note that because of the FOLD and UNFOLD rules of recursive types, the requirement that only object specifications with a μ -binder in head position occur in Σ is no real restriction. The definition of the functional Φ of Definition 4.6 remains virtually the same apart from an unfolding of the recursive specification in the cases for field and method result specifications:

Definition 6.2. Let $\mathcal{S} = \mathcal{P}(\text{St} \times \text{RSF})^{\text{StSpec}}$ denote the collection of families of subsets of $\text{St} \times \text{RSF}$, indexed by store specifications (in the sense of Definition 6.1). Table 13 defines a functional $\Phi: \mathcal{S}^{\text{op}} \times \mathcal{S} \rightarrow \mathcal{S}$; as before we write $\sigma \in [\Sigma]$ if there is some $\phi \in \text{RSF}$ such that $(\sigma, \phi) \in \text{fix}(\Phi)_\Sigma$.

The proof of Lemma 4.7 can be easily adapted to show that this functional also has a unique fixed point.

Lemma 6.3 (Existence). Functional Φ in Definition 6.2 has a unique fixpoint $\text{fix}(\Phi)$.

6.3. Semantics of Recursive Specifications

Definition 6.4. We extend the interpretation of specifications to the new cases, where η maps specification variables to admissible subsets of $\text{Val} \times \text{St}$:

$$\begin{aligned}
[\Gamma; \Delta \vdash \top] \rho \eta &= \text{Val} \times \text{St} \\
[\Gamma; \Delta \vdash X] \rho \eta &= \eta(X) \\
[\Gamma; \Delta \vdash \mu(X)A] \rho \eta &= \text{gfp}(\lambda \chi. [\Gamma; \Delta, X <: \top \vdash A] \rho \eta [X = \chi])
\end{aligned}$$

We write $\eta \models \Delta$ if, for all $X <: Y$ in Δ , $\eta(X) \subseteq \eta(Y)$.

We briefly observe the following facts, (the duals of) which are standard (Davey and Priestley, 2002).

- By Tarski's Fixed Point Theorem, every monotonic map $f : L \rightarrow L$ on a complete lattice (L, \leq) has a greatest fixed-point $\mathbf{gfp}(f)$ (which is in fact the greatest *post*-fixed point).
- If $f : L \rightarrow L$ additionally preserves meets of decreasing chains $x_0 \geq x_1 \geq \dots$, i.e., $f(\bigwedge_i x_i) = \bigwedge_i f(x_i)$, the greatest fixed point can be obtained as $\mathbf{gfp}(f) = \bigwedge \{f^n(\top) \mid n \in \mathbb{N}\}$ where \top is the greatest element of L .
- For a complete lattice (L, \leq) and any set A , the set of maps $A \rightarrow L$ forms a complete lattice when ordered pointwise, with the meet of $\{f_i \mid i \in I\}$ given by $\lambda a. \bigwedge_i f_i(a)$.
- The greatest fixed point operator is monotonic: Suppose $f \leq g$ are monotonic maps in the lattice $L \rightarrow L$, then $\mathbf{gfp}(f) \leq \mathbf{gfp}(g)$.
- Composition preserves meets of descending chains: If $f_0 \geq f_1 \geq \dots$ and $g_0 \geq g_1 \geq \dots$ are maps in $L \rightarrow L$ such that every f_i and g_j is monotonic and preserves meets of descending chains then $\bigwedge_i f_i \circ \bigwedge_j g_j = \bigwedge_n (f_n \circ g_n)$. It follows that $\mathbf{gfp}(\bigwedge_i f_i) = \bigwedge_i \mathbf{gfp}(f_i)$ i.e., \mathbf{gfp} also preserves meets of chains.

The set of admissible subsets of $\mathbf{Val} \times \mathbf{St}$, $\mathcal{Adm}(\mathbf{Val} \times \mathbf{St})$, is closed under arbitrary intersections, hence forms a complete lattice when ordered by set inclusion. Therefore, specification environments $\eta : \mathcal{SV} \rightarrow \mathcal{Adm}(\mathbf{Val} \times \mathbf{St})$ with the pointwise ordering form a complete lattice.

In the following, we show that the interpretation of specifications given above is well-defined. More specifically, we show that meets of descending chains of environments are preserved.

Lemma 6.5 (Well-definedness). $\llbracket \Gamma; \Delta \vdash A \rrbracket$ preserves meets of descending chains:

$$\eta_0 \geq \eta_1 \geq \dots \implies \llbracket \Gamma; \Delta \vdash A \rrbracket \rho(\bigwedge_i \eta_i) = \bigcap_i \llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta_i$$

In particular, this lemma shows that the greatest fixed point used in Definition 6.4 exists by the observations made above.

Proof. We can show this by induction on the structure of A . The only interesting case is where A is of the form $\mu(X)B$.

Suppose $\eta_0 \geq \eta_1 \geq \dots$. If we let $f_i : \mathcal{Adm}(\mathbf{Val} \times \mathbf{St}) \rightarrow \mathcal{Adm}(\mathbf{Val} \times \mathbf{St})$,

$$f_i(\chi) = \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho \eta_i[X = \chi], \quad i \in \mathbb{N}$$

then the induction hypothesis entails that each f_i is monotonic, and $f_0 \geq f_1 \geq \dots$ is a descending chain of environments. Moreover, since for each $i \in \mathbb{N}$ and descending chain $\chi_0 \supseteq \chi_1 \supseteq \dots$ in $\mathcal{Adm}(\mathbf{Val} \times \mathbf{St})$

$$\bigwedge_j \eta_i[X = \chi_j] = \eta_i[X = \bigcap_j \chi_j]$$

the induction hypothesis shows that each f_i preserves meets:

$$\begin{aligned} f_i(\bigcap_j \chi_j) &= \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho(\bigwedge_i \eta_i[X = \chi_j]) \\ &= \bigcap_j \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho(\eta_i[X = \chi_j]) \\ &= \bigcap_j f_i(\chi_j) \end{aligned}$$

We obtain

$$\begin{aligned} \llbracket \Gamma; \Delta \vdash A \rrbracket \rho(\bigwedge_i \eta_i) &= \mathbf{gfp}(\lambda \chi. \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho(\bigwedge_i \eta_i)[X = \chi]) && \text{by definition} \\ &= \mathbf{gfp}(\lambda \chi. \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho(\bigwedge_i \eta_i[X = \chi])) && \text{pointwise meet} \\ &= \mathbf{gfp}(\lambda \chi. \bigcap_i \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho \eta_i[X = \chi]) && \text{by induction} \\ &= \mathbf{gfp}(\bigwedge_i f_i) && \text{pointwise meet} \\ &= \bigcap_i \mathbf{gfp}(f_i) && \mathbf{gfp} \text{ preserves meet} \\ &= \bigcap_i \llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta_i && \text{by definition} \end{aligned}$$

which concludes the proof \square

Lemma 6.6 (Substitution). For all $\Gamma; \Delta, X \vdash A$, $\Gamma; \Delta \vdash B$, ρ and η ,

$$\llbracket \Gamma; \Delta, X \vdash A \rrbracket \rho(\eta[X = \llbracket \Gamma; \Delta \vdash B \rrbracket \rho \eta]) = \llbracket \Gamma; \Delta \vdash A[B/X] \rrbracket \rho \eta$$

Proof. By induction on A . \square

6.4. Syntactic Approximations

Recall the statement of Lemma 5.2, one of the key lemmas in the proof of the soundness theorem:

$$\forall \sigma, \Sigma, l, A. A \text{ closed} \wedge \sigma \in \llbracket \Sigma \rrbracket \wedge \vdash \Sigma.l <: A \implies (l, \sigma) \in \llbracket A \rrbracket \quad (22)$$

In Section 5 this was proved by induction on the structure of A . This inductive proof cannot be extended directly to prove a corresponding result for recursive specifications: The recursive unfolding in cases (F) and (M3) of Definition 6.2 would force a similar unfolding of A in the inductive step, thus not necessarily decreasing the size of A .

The remainder of this section is therefore concerned with the derivation of (22). Instead of using induction on A , we consider finite approximations as in the sense of Amadio and Cardelli (1993), where we get rid of recursion by unfolding a finite number of times and then replacing all remaining occurrences of recursion by \top . We call a specification *non-recursive* if it does not contain any occurrences of specifications of the form $\mu(X)B$.

Definition 6.7 (Approximations). For each A and each $k \in \mathbb{N}$, we define $A|_0 = \top$ and $A|_{k+1}$ by the cases given in Table 14.

Note that, as in (Amadio and Cardelli, 1993), well-definedness of approximation can be shown by a well-founded induction on the lexicographic order on k and the number of μ in head position. In particular observe that our definition of recursive specifications already ruled out troublesome cases like $\mu(X)X$.

Table 14. *Approximations*

$X ^{k+1}$	=	X
$\top ^{k+1}$	=	\top
$Bool ^{k+1}$	=	$Bool$
$\mu(X)A ^{k+1}$	=	$A[\mu(X)A/X] ^{k+1}$
$B ^{k+1}$	=	$[f_i : A_i ^{k+1}, m_j : \varsigma(y_j)B_j ^{k+1} :: T_j]_{i \in I, j \in J}$
where $B \equiv [f_i : A_i^{i=1 \dots n}, m_j : \varsigma(y_j)B_j :: T_j^{j=1 \dots m}]$		

Table 15. *The generalised object subspecification rule*

Γ	$;$	$\Delta \vdash A_i^{i=1 \dots n+p}$	Γ	$;$	$\Delta \vdash A_i <: A_i'^{i=1 \dots n}$	$\Gamma, y_j \vdash T_j^{j=1 \dots m+q}$
Γ, y_j	$;$	$\Delta \vdash B_j^{j=m+1 \dots m+q}$	Γ, y_j	$;$	$\Delta \vdash B_j <: B_j'^{j=1 \dots m}$	$\Gamma, y_j \vdash T_j'^{j=1 \dots m}$
						$\vdash_{\text{fo}} T_j \rightarrow T_j'^{j=1 \dots m}$
$\Gamma; \Delta \vdash [f_i : A_i^{i=1 \dots n+p}, m_j : \varsigma(y_j)B_j :: T_j^{j=1 \dots m+q}] <: [f_i : A_i'^{i=1 \dots n}, m_j : \varsigma(y_j)B_j' :: T_j'^{j=1 \dots m}]$						

6.4.1. *Properties of Approximations* Unfortunately, approximations $A|^{k+1}$ as defined above are not in fact approximating A (from above) with respect to the subspecification relation $<: \cdot$, the reason being the invariance in field specifications. For example, if we consider an object specification $A \equiv [f_1 : X, f_2 : Bool]$ we can observe the following:

$$\begin{aligned}
\mu(X)\mu(Y)A|^{k+1} &= [f_1 : \mu(X)\mu(Y)A, f_2 : Bool]^{k+1} \\
&= [f_1 : \mu(X)\mu(Y)A|^{k+1}, f_2 : Bool|^{k+1}] \\
&= [f_1 : [f_1 : \mu(X)\mu(Y)A, f_2 : Bool]^{k+1}, f_2 : Bool] \\
&= [f_1 : [f_1 : \mu(X)\mu(Y)A|^{k+1}, f_2 : Bool|^{k+1}], f_2 : Bool] \\
&= [f_1 : [f_1 : \top, f_2 : \top], f_2 : Bool]
\end{aligned}$$

By inspection of the rules, $\vdash \mu(X)\mu(Y)A <: \mu(X)\mu(Y)A|^{k+1}$ requires to show

$$\Gamma; \Delta \vdash [f_1 : [f_1 : \mu(X)\mu(Y)A, f_2 : Bool], f_2 : Bool] <: [f_1 : [f_1 : \top, f_2 : \top], f_2 : Bool]$$

for appropriate Γ and Δ . But subspecifications of object specifications can only be derived for equal components f_1 with the rules of Section 3.

Therefore we consider the more generous subspecification relation that also allows subspecifications in field components, by replacing the rule for object specifications with the one given in Table 15.

We write $<:^*$ for this relation, and observe that $\vdash A <: B$ implies $\vdash A <:^* B$. It is still sufficient to guarantee soundness in our case as will be shown below. First, we obtain the following approximation lemma for the $<:^*$ relation.

Lemma 6.8 (Approximation). For all specifications $\Gamma; \Delta \vdash A$, the following hold.

- 1 For all $k \in \mathbb{N}$, $\Gamma; \Delta \vdash A <:^* A|^{k+1}$.
- 2 For all $k, l \in \mathbb{N}$, $\Gamma; \Delta \vdash A|^{k+l} <:^* A|^{k+1}$.
- 3 If A is non-recursive then there exists $n \in \mathbb{N}$ such that for all $k \geq n$, $A \equiv A|^{k+1}$.

Proof. The proofs are by induction on the lexicographic order on k and the number of μ in head position, then considering cases for the specification A . \square

6.4.2. Soundness of the Subspecification

Lemma 6.9 (Soundness of $<:^*$). If $\Gamma; \Delta \vdash A <:^* B$, $\rho \in \text{Env}$ and $\eta \vDash \Delta$ then $\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta \subseteq \llbracket \Gamma; \Delta \vdash B \rrbracket \rho \eta$.

Proof. By induction on the derivation of $\Gamma; \Delta \vdash A <:^* B$.

- The cases for REFLEXIVITY and TRANSITIVITY are immediate, as is TOP.
- FOLD and UNFOLD follow from the fact that the denotation of $\mu(X)A$ is indeed a fixed point,

$$\begin{aligned} \llbracket \Gamma; \Delta \vdash \mu(X)A \rrbracket \rho \eta &= \mathbf{gfp}(\lambda \chi. \llbracket \Gamma; \Delta, X \vdash A \rrbracket \rho \eta [X = \chi]) && \text{by definition} \\ &= \llbracket \Gamma; \Delta, X \vdash A \rrbracket \rho (\eta [X = \llbracket \Gamma; \Delta \vdash \mu(X)A \rrbracket \rho \eta]) && \text{fixed point} \\ &= \llbracket \Gamma; \Delta \vdash A[\mu(X)A/X] \rrbracket \rho \eta && \text{by Lemma 6.6} \end{aligned}$$

- The case of the (generalised) object subspecification rule SUBOBJECT follows by induction and is rather straightforward.
- Finally, in the case of the SUBREC rule, suppose that $\Gamma; \Delta \vdash \mu(X)A <:^* \mu(Y)B$ has been derived from $\Gamma; \Delta, Y <: \top, X <: Y \vdash A <:^* B$. We use the fact that $\llbracket \Gamma; \Delta \vdash \mu(Y)B \rrbracket \rho \eta$ is the greatest post-fixed point of the map

$$f(\chi) = \llbracket \Gamma; \Delta, Y \vdash B \rrbracket \rho \eta [X = \chi]$$

which is monotonic as shown in Lemma 6.5. Since $\alpha = \llbracket \Gamma; \Delta \vdash \mu(X)A \rrbracket \rho \eta$ is a fixed point of $\lambda \chi. \llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta [X = \chi]$ we calculate

$$\begin{aligned} \alpha &= \llbracket \Gamma; \Delta, X, Y \vdash A \rrbracket \rho \eta [X = \alpha, Y = \alpha] && \Gamma; \Delta, X \vdash A \text{ independent of } \eta(Y) \\ &\subseteq \llbracket \Gamma; \Delta, X, Y \vdash B \rrbracket \rho \eta [X = \alpha, Y = \alpha] && \text{by induction} \\ &= f(\alpha) && \Gamma; \Delta, Y \vdash B \text{ independent of } \eta(X) \end{aligned}$$

which shows α is a post-fixed point of f . Hence, $\llbracket \Gamma; \Delta \vdash \mu(X)A \rrbracket \rho \eta = \alpha \subseteq \mathbf{gfp}(f) = \llbracket \Gamma; \Delta \vdash \mu(Y)B \rrbracket \rho \eta$ as required. \square

6.4.3. *Relating Semantics and Syntactic Approximations* Taken together, Lemma 6.9 and Lemma 6.8(1) show $\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta \subseteq \llbracket \Gamma; \Delta \vdash A|^{k} \rrbracket \rho \eta$ for all $\eta \vDash \Delta$ and $k \in \mathbb{N}$; in particular,

$$\llbracket A \rrbracket \eta \subseteq \bigcap_{k \in \mathbb{N}} \llbracket A|^{k} \rrbracket \eta \tag{23}$$

for closed specifications A . For the reverse inclusion, we use the characterisation of greatest fixed points as meet of a descending chain, which is in close correspondence with the syntactic approximations.

Lemma 6.10 (Combining Substitution and Approximation). For all specifications A, B , all X such that $\Gamma; \Delta \vdash B$ and $\Gamma; \Delta, X \vdash A$, and for all $k, l \in \mathbb{N}$

$$\Gamma; \Delta \vdash A[B/X]|^l <:^* A[B|^{k}/X]|^l$$

In particular, by Lemma 6.9, $\llbracket \Gamma; \Delta \vdash A[B/X]^l \rrbracket \rho \eta \subseteq \llbracket \Gamma; \Delta \vdash A[B^k/X]^l \rrbracket \rho \eta$, for all $\eta \vDash \Delta$.

Proof. By induction on the lexicographic order on l and the number of μ in head position.

- Case $l = 0$. Clearly $\Gamma; \Delta \vdash A[B/X]^0 <:^* \top = A[B^k/X]^0$.
- Case $l > 0$. We consider possible cases for A .
 - A is X . Then $\Gamma; \Delta \vdash A[B/X]^l = B^l <:^* B^k = A[B^k/X]^l$.
 - A is \top , $Bool$ or $Y \neq X$. Then $\Gamma; \Delta \vdash A[B/X]^l = A^l <:^* A^l = A[B^k/X]^l$.
 - A is $[f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$. This case follows again easily by induction hypothesis.
 - A is $\mu(Y)C$, without loss of generality Y not free in B . Then by induction hypothesis we find $\Gamma; \Delta \vdash C[A/Y][B/X]^l <:^* C[A/Y][B^k/X]^l$. Using properties of syntactic substitutions, we calculate

$$\begin{aligned}
A[B/X]^l &\equiv \mu(Y)(C[B/X])^l && \text{substitution} \\
&\equiv C[B/X][(\mu(Y)(C[B/X]))/Y]^l && \text{definition of } (-)^l \\
&\equiv C[B/X][(A[B/X])/Y]^l && \text{substitution} \\
&\equiv C[A/Y][B/X]^l && Y \text{ not free in } B
\end{aligned}$$

and analogously $C[A/Y][B^k/X]^l = A[B^k/X]^l$, which entails the result. \square

Lemma 6.11 (Approximation of Specifications). For all $\Gamma; \Delta \vdash A$, $\rho \in \text{Env}$ and environments $\eta \vDash \Delta$, $\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta = \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A^k \rrbracket \rho \eta$.

Proof. By (23), all that remains to show is $\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta \supseteq \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A^k \rrbracket \rho \eta$. We proceed by induction on the lexicographic order on pairs (M, A) where M is an upper bound on the number of μ -binders in A . For the base case, $M = 0$, by Lemma 6.8(3) there exists $n \in \mathbb{N}$ such that for all $k \geq n$, $A^k = A$, and so in fact

$$\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta = \llbracket \Gamma; \Delta \vdash A^n \rrbracket \rho \eta \supseteq \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A^k \rrbracket \rho \eta$$

Now suppose that A contains at most $M + 1$ μ binders. We consider cases for A .

- Case A of the form \top , X or $Bool$. Then as above, there exists $n \in \mathbb{N}$ such that for all $k \geq n$, $A^k = A$ and we are done.
- Case A is $[f_i: A_i^{i=1\dots n}, m_j: \varsigma(y_j)B_j::T_j^{j=1\dots m}]$. Then, by induction hypothesis,

$$\llbracket \Gamma; \Delta \vdash A_i \rrbracket \rho \eta \supseteq \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A_i^k \rrbracket \rho \eta$$

and

$$\llbracket \Gamma, y_j; \Delta \vdash B_j \rrbracket (\rho[y_j := l]) \eta \supseteq \bigcap_{k \in \mathbb{N}} \llbracket \Gamma, y_j; \Delta \vdash B_j^k \rrbracket (\rho[y_j := l]) \eta$$

for $1 \leq i \leq n$ and $1 \leq j \leq m$. Hence, if $(l, \sigma) \in \llbracket \Gamma; \Delta \vdash A^k \rrbracket \rho \eta$ for all $k \in \mathbb{N}$ then

$$(\sigma.l.f_i, \sigma) \in \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A_i^k \rrbracket \rho \eta \subseteq \llbracket \Gamma; \Delta \vdash A_i \rrbracket \rho \eta$$

and $\sigma.l.m_j(\sigma) = (v, \sigma')$ implies

$$(v, \sigma') \in \bigcap_{k \in \mathbb{N}} \llbracket \Gamma, y_j; \Delta \vdash B_j |^k \rrbracket (\rho[y_j := l]) \eta \subseteq \llbracket \Gamma, y_j; \Delta \vdash B_j \rrbracket (\rho[y_j := l]) \eta$$

by the definition of $A|^k$. This shows $(l, \sigma) \in \llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta$ as required.

— A is $\mu(X)B$. Recall that

$$\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta = \mathbf{gfp}(f_A)$$

is the greatest *post*-fixed point of $f_A(\chi) = \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho \eta [X = \chi]$. We show that $\alpha := \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A|^k \rrbracket \rho \eta$ is a post-fixed point of f_A , from which

$$\llbracket \Gamma; \Delta \vdash A \rrbracket \rho \eta \supseteq \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A|^k \rrbracket \rho \eta$$

then follows: First note that by Lemma 6.8(2) and Lemma 6.9

$$\eta[X = \llbracket \Gamma; \Delta \vdash A|^0 \rrbracket \rho \eta] \geq \eta[X = \llbracket \Gamma; \Delta \vdash A|^1 \rrbracket \rho \eta] \geq \dots$$

forms a descending chain of environments. Hence we can calculate

$$\begin{aligned} f_A(\alpha) &= \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho \eta [X = \alpha] && \text{definition of } f_A \\ &= \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho (\bigwedge_k \eta[X = \llbracket \Gamma; \Delta \vdash A|^k \rrbracket \rho \eta]) && \text{definition of } \alpha \text{ and meets} \\ &= \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta, X \vdash B \rrbracket \rho \eta [X = \llbracket \Gamma; \Delta \vdash A|^k \rrbracket \rho \eta] && \text{Lemma 6.5, meets} \\ &= \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash B[A|^k/X] \rrbracket \rho \eta && \text{Lemma 6.6, substitution} \\ &\supseteq \bigcap_{k \in \mathbb{N}} \bigcap_{l \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash B[A|^k/X]^l \rrbracket \rho \eta && \text{induction hypothesis} \\ &\supseteq \bigcap_{l \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash B[A/X]^l \rrbracket \rho \eta && \text{Lemma 6.10} \\ &= \bigcap_{k \in \mathbb{N}} \llbracket \Gamma; \Delta \vdash A|^k \rrbracket \rho \eta && \text{definition of } \mu(X)A^k \end{aligned}$$

i.e. $\alpha \subseteq f_A(\alpha)$. Note that we can apply induction in the fourth line since $A|^k$ does not contain any μ and therefore $B[A|^k/X]$ contains at most M μ -binders.

This concludes the proof. \square

6.5. Soundness

After the technical development in the preceding subsection we can now prove (22). From this result the soundness proof of the logic extended with recursive specifications then follows, along the lines of the proof presented in Section 5 for non-recursive specifications.

Lemma 6.12. For all $\sigma \in \text{St}$, $\Sigma \in \text{StSpec}$, $l \in \text{Loc}$ and closed A , if $\sigma \in \llbracket \Sigma \rrbracket$ and $\vdash \Sigma.l <:^* A$ then $(l, \sigma) \in \llbracket A \rrbracket$.

Proof. The proof proceeds by considering finite specifications first. This can be proved by induction on A , as in Lemma 5.2. When applying the induction hypothesis we use the fact that $\vdash A <: B$ implies $\vdash A <:^* B$.

To extend the proof to all (possibly recursive) specifications, note that by Lemma 6.8, $\vdash A <:^* A|^k$ for all $k \in \mathbb{N}$, which entails $\vdash \Sigma.l <:^* A|^k$ for all k by transitivity. Every $A|^k$ is non-recursive, so by the above considerations, $(l, \sigma) \in \llbracket A|^k \rrbracket$ for all k . Thus

$$(l, \sigma) \in \bigcap_{k \in \mathbb{N}} \llbracket A|^k \rrbracket = \llbracket A \rrbracket$$

by Lemma 6.11. □

7. Outlook

The study of Abadi-Leino logic from a denotational viewpoint was not just carried out for advertising denotational techniques, nor for the belief that it is the best logic one can devise. However, it was the first (and, to the best of our knowledge, so far the only) logic for the object-calculus and thus an ideal playground and starting point for our research programme.

Our long-term objective is to design a better, more powerful and more complete logic building on the lessons learnt from analysing Abadi-Leino logic. To that end, we plan to carry out the following extensions or changes of Abadi and Leino’s calculus. We strongly believe that the denotational approach will guide us in finding the right rules (and a modular correctness proof):

Local Store. In this paper we have worked with a global store model. Every object, its field and methods, are visible to any other object. For Abadi-Leino logic this was sufficient but one significant feature of object-oriented programs is *encapsulation*. Encapsulation is modelled only by a refined notion of store – and accordingly more refined store specifications. Reddy and Yang (2004) and Benton and Lepercqey (2005) have presented such models for higher-order languages with storable references (but no higher-order store). Their models give rise to a large number of correct program equivalences, and the authors expressed the need to extend their respective models to a full object-oriented language and to specifications. Coming from the other end, we have a logic for a simple object-oriented language, but need to incorporate locality and encapsulation.

A complementary approach to information hiding is to restrict the language by imposing a *confinement* condition on programs. Banerjee and Naumann (2005) use this approach to prove representation independence for a class-based Java-like language. It should be interesting to try similar techniques for a language with higher-order store, such as the object calculus, in order to prove a restricted form of encapsulation and representation independence.

Invariants of fields. Abadi and Leino’s logic is peculiar in that verified programs need to preserve store specifications. Put differently, only properties which are in fact preserved can be expressed by object specifications. In particular, specifying fields in object specifications is limited. Invariants like e.g. `balance ≥ 0`, stating that an account comes without overdraft, cannot be formulated. Note that such an axiom in a transition specification only guarantees that the *current* balance is positive. Using a store with local fields (as described above), such invariants can be accommodated. Invariance of such a field has to be established only for those methods that can see it.

Method Parameters. Formal method parameters of the form $x:A$ can be attached to method specifications — e.g. `deposit(x:Int): $\zeta(y)$` — by adding an extra assumption to the definition of store specifications. When $\sigma' \in \llbracket \Sigma' \rrbracket$ then conditions (M1)–

(M3) have to be shown for all $v \in \|A\|_{\Sigma}$, where v is the actual parameter replacing formal parameter x in the method call. There are limitations, however, as the resulting object specification must still allow for subspecifications. In particular, its semantics should not be defined by a recursion with negative occurrences of store.

Dynamic Loading. Dynamic loading of objects is, in a way, already available in the object calculus (and this is one of its advantages over class-based languages). Loading an object of which one only knows its specification $A \equiv [f_i : A_i; m_j : \zeta(x_j)B_j :: T_j]$ corresponds to using a command of which one only knows its result specification A . Thus, $x : [\text{load} : \zeta(y)A :: \exists \bar{z}. T_{\text{obj}}(\bar{f} = \bar{z})] \vdash x.\text{load} : A :: \exists \bar{z}. T_{\text{obj}}(\bar{f} = \bar{z})$ simulates dynamic loading where x may be thought of as class loader, and where the load command is $x.\text{load}$. If A is simply $[],$ nothing is known about the loaded object. In this case one has to assume another command to check at runtime whether a given object fulfils a given specification. This implies that specifications have to be representable in the programming language and thus a form of *reflection*.

Recursive Specifications. Recursive specifications are necessary when a field of an object or a result of one of the object's methods are supposed to satisfy the same specification as the object itself. As outlined at the beginning of Section 6 they are needed to implement recursive datatypes such as lists and trees. In the preceding section we have discussed how the logic can be safely enriched by recursive specifications.

Parametric Method Specifications. Transition specifications in Abadi-Leino logic cannot refer to methods. This is unnecessary as method specifications are fixed at object introduction and assumed to be invariant afterwards. But for programs that, for instance, use delegations (similar to the Command pattern of Gamma et al., 1995) this is not adequate: The specification in use is not known at the time of object creation but only at update (and it may change with further updates). As a remedy one could allow placeholders for specifications (B and T) that can be shared inside objects. For example let X and Y be such placeholders then $[f : [n : \zeta(x)X::Y], m : \zeta(x)X::Y]$ states that m satisfies the same method specification that n satisfies. Note that only n can be updated via f . The invariance of specification still holds, it is just that every object providing a method n will meet specification $[n : \zeta(x)X::Y]$ and m will still satisfy $m : \zeta(x)X::Y$ if it is implemented as $m = \zeta(y)x.f.n$. More general transition specifications for m are conceivable that assume Y to hold only for certain calls of n . The restrictions revealed by the existence theorem may turn out useful to find the right semantics for such specifications.

Method Update. Although method update is not allowed in Abadi-Leino logic, fields can be updated and thus the methods in a field object, similar to the Decorator pattern (Gamma et al., 1995) as seen in the example above. By the invariance of field components of object specifications, the object used for the update must satisfy the specification of the field to be updated. Any extra conditions that the new object may fulfil are not recorded in the logic and cannot be used later. More useful would be a "behavioural" update where result and transition specifications of the overriding method are subspecifications

of the original method. But this would require a relaxation of the idea of invariance of store specifications.

Invariance of Store Specifications. The previous discussion shows the need for a logic where object specifications are not always preserved or one may want to refine the object specifications. It seems worthwhile to develop a calculus that makes invariance properties explicit in the logic. Even though this may clutter proofs (for *users* of such a logic), it may reveal limitations of logics with higher-order *dynamic* store. Moreover, it is expected that Separation Logic (O’Hearn et al, 2001; Reynolds, 2002) provides support for local reasoning. Yet, this requires more research to get Separation Logic married with Higher-order store first.

As a consequence, it should be possible to devise more practical and more expressive program logics. It may also be instructive to derive a class-based logic by translating classes into objects (Abadi and Cardelli, 1996) using the object-calculus. Therein dynamic (class) loading is easy to model.

8. Conclusion

Based on a denotational semantics, we have given a soundness proof for Abadi and Leino’s program logic of an object-based language. Compared to the original proof, which was carried out with respect to an operational semantics, our techniques allowed us to distinguish the notions of derivability and validity. Further, we used the denotational framework to extend the logic to recursive object specifications. In comparison to a similar logic presented in (Leino, 1998) our notion of subspecification is structural rather than nominal.

Although our proof is very much different from the original one, the nature of the logic forces us to work with store specifications too. Information for locations referenced from the environment Γ will be needed for derivations. Since the context Γ cannot reflect the dynamic aspect of the store (which is growing) one uses store specifications Σ . They do not show up in the rules of Abadi-Leino logic as they are automatically preserved by programs. This is shown as part of the soundness proof rather than being a proof obligation on the level of derivations. By contrast to (Abadi and Leino, 2004), we can view store specifications as predicates on stores which need to be defined by mixed-variant recursion due to the form of the object introduction rule. Unfortunately, such recursively defined predicates do not directly admit an interpretation of either subsumption or weakening. This led us to a *positive recursive* semantics of individual objects, for which the set containment models the syntactic subspecification relation (cf. Lemma 3.5).

Conditions (M1)–(M3) in the semantics of store specifications ensure that methods in the store preserve not only the current store specification but also arbitrary extensions $\Sigma' \succ \Sigma$. This accounts for the (specifications of) objects allocated between definition time and call time.

Clearly, not every predicate on stores is preserved. As we lack a semantic characterisation of those specifications that are syntactically definable (as Σ), specification syntax appears in the definition of $\sigma \in \llbracket \Sigma \rrbracket$ (Definition 4.6). More annoyingly, field update

requires subspecifications to be invariant in the field components, otherwise even type soundness is invalidated. We do not know how to express this property of object specifications semantically (on the level of predicates) and need to use the inductively defined syntactic subspecification relation instead.

The proof of Theorem 4.7, establishing the existence of store predicates, provides an explanation why transition relations of the Abadi-Leino logic express properties of the flat part of stores only: Semantically, a (sufficient) condition is that transition relations are upwards and downwards closed in their first and second store argument, respectively.

In Section 7 we have described some of the limitations of Abadi-Leino logic and sketched possible improvements. The results established in this paper pave the way for this line of research.

Acknowledgement We wish to thank Thomas Streicher for discussions and comments. The DOMAINS Workshops have been a constant source of inspiration to us and we are grateful to Professor Klaus Keimel for having kicked off this series in Darmstadt in 1994.
